1 Introduction

The TAS3103 is a fully configurable digital audio processor that preserves high-quality audio by using a 48-bit data path, 28-bit filter coefficients, and a single cycle 28 x 48-bit multiplier and 76-bit accumulator. Because of the coefficient-configurable fixed-program architecture of the TAS3103, a complete set of user-specific audio processing functions can be realized, with short development times, in a small, low power, low-cost device. A personal computer (PC) GUI-based software development package and a comprehensive evaluation board provide additional facilities to further reduce development times. The TAS3103 uses 1.8-V core logic with 3.3-V I/O buffers, and requires only 3.3-V power. The TAS3103 is available in a 38-pin TSSOP package.

1.1 Features

- Audio Input/Output
 - Four Serial Audio Input Channels
 - Three Serial Audio Output Channels
 - 8-kHz to 96-kHz Sample Rates Supported
 - 15 Stereo/TDM Data Formats Supported
 - Input/Output Data Format Selections Independent
 - 16-, 18-, 20-, 24-, and 32-Bit Word Sizes Supported
- Serial Master/Slave I²C Control Channel
- Three Independent Monaural Processing Channels
 - Programmable Four Stereo Input Digital Mixer
 - 3D Effect and Reverb Structure and Filters
 - Programmable 12 Band Digital Parametric EQ
 - Programmable Digital Bass and Treble Controls
 - Programmable Digital Soft Volume Control (24 dB to $-\infty$ dB)
 - Soft Mute/Unmute
 - Programmable Dither
 - Programmable Loudness Compensation
 - VU Meter and Spectral Analysis I²C Output
 - Programmable Channel Delay (Up to 42 ms at 48 kHz)
 - 192-dB Dynamic Range (Supports Up to 32-Bit Audio Data)
 - Dual Threshold Dynamic Range Compression/Expansion
- Electrical and Physical
 - Single 3.3-V Power Supply
 - 38-Pin TSSOP Package
 - Low Power Standby

1.2 Terminal Assignments

1.3 Hardware Block Diagram

1.4 Functional Block Diagram

1.5 Ordering Information

T _A	PLASTIC 38-PIN TSSOP (DBT)
0°C to 70°C	TAS3103DBT
-40°C to 85°C	TAS3103IDBT

1.6 Terminal Functions

TERMINAL				DESCRIPTION	PULLUP/ DOWN(2)
NAME	NO.	I/O	TYPE(1)		
A_VDDS (3.3 V)	7		PWR	The PWR pin is used to input 3.3-V power to the DPLL and clock oscillator. This pin can be connected to the same power source used to drive the DVSS power pin. To achieve low DPLL jitter, this pin should be bypassed to AVSS with a 0.01- μ F capacitor (low ESR preferable).	None
AVDD_BYPASS_CAP	6		PWR	AVDD_BYPASS_CAP is a pinout of the internally regulated 1.8-VDC power used by the DPLL and crystal oscillator. This pin should be connected to pin 8 with a 0.01- μ F capacitor (low ESR preferable). This pin must not be used to power external devices.	None
AVSS	8		PWR	AVSS is the ground reference for the internal DPLL and oscillator circuitry. This pin needs to reference the same ground as DVSS power pin. To achieve low DPLL jitter, ground noise at this pin must be minimized. The availability of the AVSS pin allows a designer to use optimizing techniques such as star ground connections, separate ground planes, or other quiet ground distribution techniques to achieve a quiet ground reference at this pin.	None
CS0	24	I	D	CS0 is the LSB of a 2-bit code used to generate part of an I ² C device address that makes it possible to address four TAS3103 ICs on the same bus without additional chip select logic. The pulldowns on the inputs select 00 as a default when neither pin is connected.	Pulldown
CS1	25	I	D	CS1 is the MSB of a 2-bit code used to generate part of an I ² C device address that makes it possible to address four TAS3103 ICs on the same bus without additional chip select logic.	Pulldown
DVDD_BYPASS_CAP	29		PWR	DVDD_BYPASS_CAP is a pin-out of the internally regulated 1.8-V power used by all internal digital logic. This pin must not be used to power external devices. A low ESR capacitor of at least 470 nF should be placed as close to the device as possible between this pin and pin 28.	None
DVSS	28		PWR	DVSS is the digital ground pin.	None
GPIO0	18	I/O	D	GPIO0 is a general-purpose I/O, controlled by the internal microprocessor through I ² C commands. When in the I ² C master mode, GPIO0 serves as a volume up command for CH1/CH2.	Pullup
GPIO1	19	I/O	D	GPIO1 is a general-purpose I/O, controlled by the internal microprocessor through I ² C commands. When in the I ² C master mode, GPIO1 serves as a volume down command for CH1/CH2.	Pullup
GPIO2	20	I/O	D	GPIO2 is a general-purpose I/O, controlled by the internal microprocessor through I ² C commands. When in the I ² C master mode, GPIO2 serves as a volume up command for CH3.	Pullup
GPIO3	21	I/O	D	GPIO3 is a general-purpose I/O, controlled by the internal microprocessor through I ² C commands. When in the I ² C master mode, GPIO3 serves as a volume down command for CH3.	Pullup
I ² CM_S	27	I	D	I ² CM_S is a non-latched input that determines whether the TAS3103 acts as an I ² C master or slave. Logic high, or no connection, sets the TAS3103 as an I ² C master device. A logic low sets the TAS3103 as an I ² C slave device. As a master I ² C device, the TAS3103 I ² C port must have access to an external EEPROM for input.	Pullup

TERMINAL				DESCRIPTION	PULLUP/ DOWN(2)
NAME	NO.	I/O	TYPE(1)		
I2C_SCL	13	I/O	D	I2C_SCL is the I ² C clock pin. When the TAS3103 I ² C port is a master, I2C_SCL is $(1/2^N) \times (1/(M+1)) \times 1/10$ times the microprocessor clock, where N and M are set to 2 and 8 respectively. When the TAS3103 I ² C port is a slave, input clock rates up to 400 kHz can be supported. This pin must be provided an external pullup (5 k Ω is recommended for most applications).	External pullup required
I2C_SDA	12	I/O	D	I2C_SDA is the I ² C bidirectional data pin. The TAS3103 I ² C port can support data rates up to 400K bits/sec. This pin must be provided an external pullup (5 k Ω is recommended for most applications).	External pullup required
LRCLK	38	I/O	D	LRCLK is either an input or an output, depending on whether the TAS3103 is in a master or slave serial audio port mode, which is determined by bit 22 of subaddress 0xF9.	Pulldown
MCLKI	9	I	D	MCLKI is a master clock input that provides an alternative to using a fixed crystal frequency. In DPLL modes, the input frequency of this clock can range from 2.8 MHz to 24.576 MHz. In PLL bypass mode, frequencies up to 136 MHz can be used. Whenever MCLKI is not used and XTALI/XTALO provide the master clock input, MCLKI must be grounded.	None
MCLKO	34	O	D	MCLKO is the master output clock pin. It is produced by dividing MCLKI/XTALI by 1, 2, or 4 (depending on the setting of a subaddress control field). MCLKO is provided to interconnect, without the need for additional glue logic, the TAS3103 interfaces chips that require different multiples of the audio sample rate (F_s) as a master clock.	None
MICROCLK_DIV	11	I	D	MICROCLK_DIV sets the division ratio between the digital audio processing clock and the internal microprocessor clock. The audio-processing clock is the DPLL output clock if PLL_bypass is not enabled. The audio-processing clock is MCLKI/XTALI master clock if PLL_bypass is enabled. Logic high on this pin sets the microprocessor clock equal to the audio-processing clock. A logic low sets the microprocessor clock to 1/4 the digital audio-processing clock. MICROCLK_DIV must be set low if the audio processing clock is > 36 MHz. MICROCLK_DIV must be set high if the audio processing clock is \leq 36 MHz.	Pulldown
ORIN	37	I	D	ORIN allows the processing of a multichannel signal set through two TAS3103s without any additional components. One use of ORIN would be to fully emulate a 6-channel audio processor at speeds up to a 96-kHz sample rate with only two TAS3103s and no glue logic. The two-chip configuration is accomplished by wiring the SDOUT1 port of one of the two TAS3103 chips to the ORIN port of the second TAS3103. Internal to the chip, the ORIN input is OR'ed with internal SDOUT1 data to generate the resulting output data on channel SDOUT1. For TDM output formats, the SDOUT1 outputs of the two chips differ in phasing in both the left and right channels to arrive at the proper composite output. For discrete outputs, one chip contributes the left channel of the composite SDOUT1, and the other chip contributes the right channel of the composite SDOUT1. If not used, ORIN must be connected to ground.	Pulldown
PLL0	22	I	D	PLL0 is the LSB of a 2-bit code used to select four different modes of DPLL multiplexer/input divider operation. PLL[1:0] values of 00, 01, and 10 select the DPLL input clock to be MCLKI/XTALI divided by 1, 2, and 4 respectively. A value of 11 results in MCLKI/XTALI being substituted for the DPLL output. The pullup/pulldown combination provides a default of 01 when neither pin is connected.	Pullup
PLL1	23	I	D	PLL1 is the MSB of a 2-bit code used to select four different modes of DPLL multiplexer/input divider operation. PLL[1:0] values of 00, 01, and 10 select the DPLL input clock to be MCLKI/XTALI divided by 1, 2, and 4 respectively. A value of 11 results in MCLKI/XTALI being substituted for the DPLL output. The pullup/pulldown combination provides a default of 01 when neither pin is connected.	Pulldown

TERMINAL				DESCRIPTION	PULLUP/ DOWN(2)
NAME	NO.	I/O	TYPE(1)		
PWRDN	2	I	D	PWRDN powers down all logic and stops all clocks whenever logic high is applied. However, the coefficient memory remains stable through a power down cycle, as long as a reset is not sent after a power down cycle.	Pulldown
REGULATOR_EN	3	I	D	REGULATOR_EN is only used in factory tests. This pin should always be tied to ground.	None
RST	26	I	D	RST is the master reset input. Applying a logic low to this pin generates a master reset. The master reset results in all coefficients being set to their power-up default state, all data memories being cleared, and all logic signals being returned to their default values.	Pullup
SCLKIN	1	I	D	SCLKIN is the serial audio port (SAP) input data clock. This clock is only used when the SAP is a slave. In master mode, SCLKOUT1 internally provides the serial input clock (SCLKOUT1 from a given TAS3103 must not be connected to SCLKIN on the same TAS3103 chip).	Pulldown
SCLKOUT1	35	O	D	SCLKOUT1 is one of two serial output bit clocks. It is divided from MCLKI/XTALI in master mode, and SCLKIN in slave mode. Subaddress control fields determine the divide ratio in both cases. When the serial audio port is in a master mode, SCLKOUT1 is used to receive incoming serial data and should be wired to the data source(s) providing data to the SDIN inputs.	None
SCLKOUT2	36	O	D	SCLKOUT2 is one of two serial output bit clocks. It is divided from MCLKI/XTALI in master mode, and SCLKIN in slave mode. Subaddress control fields determine the divide ratio in both cases. SCLKOUT2 is always used to clock out serial data from the three serial SDOOUT output data channels. SCLKOUT2 is provided separately from SCLKOUT1 to allow discrete in to TDM out and TDM in to discrete out data format conversions without the use of external glue logic.	Output
SDIN1	14	I	D	SDIN1, SDIN2, SDIN3, and SDIN4 are the four TAS3103 serial data input ports. All four input ports support four discrete (stereo) data formats. SDIN1 is the only data input port that also supports eleven time division multiplexed data formats. All four ports are capable of receiving data with bit rates up to 24.576 MHz.	Pulldown
SDIN2	15	I	D	SDIN2 is one of the four TAS3103 serial data input ports. SDIN2 supports four discrete (stereo) data formats, and is capable of receiving data with bit rates up to 24.576 MHz.	Pulldown
SDIN3	16	I	D	SDIN3 is one of the four TAS3103 serial data input ports. SDIN4 supports four discrete (stereo) data formats, and is capable of receiving data with bit rates up to 24.576 MHz.	Pulldown
SDIN4	17	I	D	SDIN4 is one of the four TAS3103 serial data input ports. SDIN4 supports four discrete (stereo) data formats, and is capable of receiving data with bit rates up to 24.576 MHz.	Pulldown
SDOUT1	30	O	D	SDOUT1, SDOUT2, and SDOUT3 are the three TAS3103 serial data output ports. All three output ports support four discrete (stereo) data formats. SDOUT1 is the only data output port that also supports eleven time division multiplexed data formats. All three ports are capable of outputting data at bit rates up to 24.576 MHz.	None
SDOUT2	32	O	D	SDOUT2 is one of the three serial data output ports. SDOUT2 supports four discrete (stereo) data formats, and is capable of outputting data at bit rates up to 24.576 MHz.	None
SDOUT3	33	O	D	SDOUT3 is one of the three serial data output ports. SDOUT3 supports four discrete (stereo) data formats, and is capable of outputting data at bit rates up to 24.576 MHz.	None
TEST	10	I	D	TEST is only used in factory tests. This pin must be left unconnected or grounded.	Pulldown

TERMINAL				DESCRIPTION	PULLUP/ DOWN(2)
NAME	NO.	I/O	TYPE(1)		
VDDS (3.3 V)	31	-	PWR	VDDS is the 3.3-V pin that powers (1) the 1.8-V internal power regulator used to supply logic power to the chip and (2) the I/O ring. It is recommended that this pin be bypassed to DVSS (pin 28) with a low ESR capacitor in the range of 0.01 μ F.	None
XTALI (1.8-V logic)	4	I	A	XTALO and XTALI provide a master clock for the TAS3103 via use of an external fundamental mode crystal. XTALI is the 1.8-V input port for the oscillator circuit. See Note 3 for recommended crystal type and accompanying circuitry. This pin should be grounded when the MCLKI pin is used as the source for the master clock.	None
XTALO (1.8-V logic)	5	O	A	XTALO and XTALI provide a master clock for the TAS3103 via use of an external fundamental mode crystal. XTALO is the 1.8-V output drive to the crystal. XTALO can support crystal frequencies between 2.8 MHz and 20 MHz. See Note 3 for recommended crystal type and accompanying circuitry. This pin should be left unconnected in applications using an external clock input to MCLKI.	None

- NOTES:
1. TYPE: A = analog; D = 3.3-V digital; PWR = power/ground/decoupling
 2. All pullups are 20- μ A weak pullups and all pulldowns are 20- μ A weak pulldowns. The pullups and pulldowns are included to assure proper input logic levels if the pins are left unconnected (pullups => logic 1 input; pulldowns => logic 0 input). Devices that drive inputs with pullups must be able to sink 20 μ A while maintaining a logic 0 drive level. Devices that drive inputs with pulldowns must be able to source 20 μ A, while maintaining a logic 1 drive level.
 3. Crystal type and recommended circuit:

- Crystal type = parallel-mode, fundamental-mode crystal
- r_d = drive level control resistor—vendor specified
- C_L = Crystal load capacitance (capacitance of circuitry between the two terminals of the crystal)
- $C_L = (C_1 \times C_2) / (C_1 + C_2) + C_S$ (where C_S = board stray capacitance \sim 2 pF)
 - Example: Vendor recommended $C_L = 18$ pF, $C_S = 3$ pF $\Rightarrow C_1 = C_2 = 2 \times (18 - 3) = 30$ pF

1.7 Operational Modes

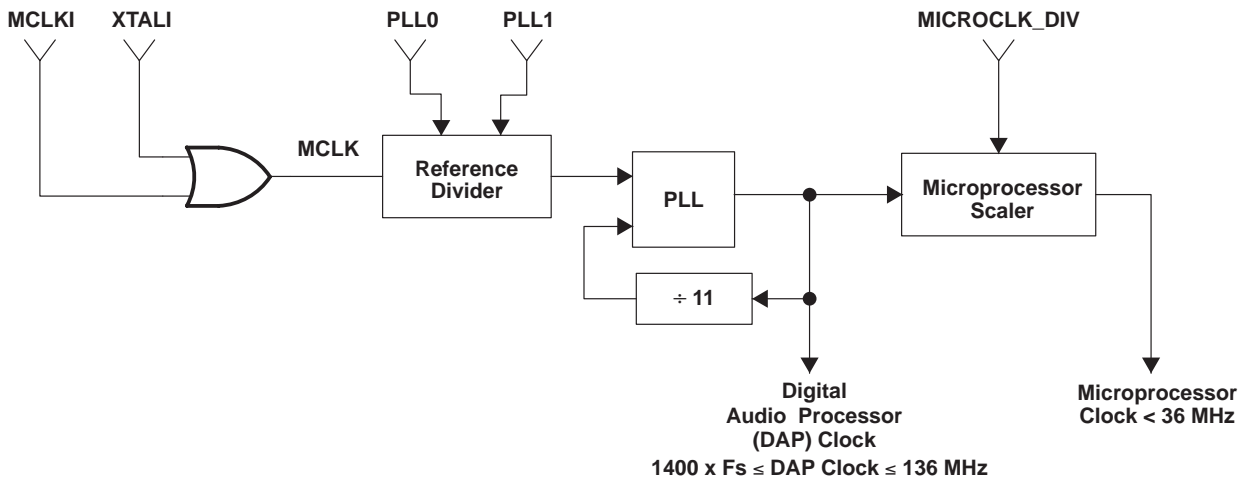

The TAS3103 operation is governed by I/O terminal voltage level settings and register / coefficient settings within the TAS3103. The terminal settings are wholly sufficient to address all external environments - allowing the remaining configuration settings to be determined by either I²C commands or by the content of an I²C serial EEPROM (when the I²C master mode is selected).

1.7.1 Terminal-Controlled Modes

1.7.1.1 Clock Control

PLL1	PLL0	DAP CLOCK
0	0	11 x MCLK
0	1	(11 x MCLK)/2
1	0	(11 x MCLK)/4
1	1	MCLK (PLL bypass)

I²S FORMAT, CLOCK MANAGEMENT, AND I²C M AND N ASSIGNMENTS

AB assigns TDM time slots for those TDM outputs involving two TAS3103s. For these output formats, one of the TAS3103 chips must be defined as AB = 0. The other TAS3103 chip must be defined as AB = 1.

Word Size Code†			Word Size

2 Hardware Architecture

Figure 2–1 depicts the hardware architecture of the chip. The architecture consists of five major blocks:

- Input Serial Audio Port (SAP)
- Output Serial Audio Port (SAP)
- DPLL and Clock Management
- Controller
- Digital Audio Processor (DAP)

Figure 2-1. TAS3103 Detailed Hardware Block Diagram

2.1 Input and Output Serial Audio Ports (SAPs)

The TAS3103 accepts data in various serial data formats including left/right justified and I²S, 16 through 32 bits, discrete, or TDM. Sample rates from 8 kHz through 96 kHz are supported. Each TAS3103 has four input serial ports and three output serial ports, labeled SDIN[4:1] and SDOUT[3:1] respectively. All ports accommodate stereo data formats, and SDIN1 and SDOUT1 also accommodate time-division multiplex (TDM) data formats. The formats are selectable via I²C commands. All input channels are assigned the same format and all output channels are assigned the same format; and the two formats need not be the same. The TAS3103 can accommodate system architectures that require data format conversions without the need for additional glue logic. If a TDM format is selected for the input port, only SDIN1 is active; the other three input channels cannot be used. If a TDM format is selected for the output port, only SDOUT1 is active; the other two channels cannot be used.

2.1.1 SAP Configuration Options

The TAS3103 serial interface data format options for discrete (stereo) data are detailed in Figure 2–2.

Figure 2–2. Discrete Serial Data Formats

When the TAS3103 is transmitting serial data, it uses the negative edge of SCLK to output a new data bit. The TAS3103 samples incoming serial data on the rising edge of SCLK.

The TDM modes on the TAS3103 only provide left justified and I²S formats, and each word in the TDM data stream adheres to the bit placement shown in Figure 2–2. Figure 2–3 illustrates the output data stream for a 4-channel TDM mode. Two cases are illustrated; an I²S data format case (SAP output mode 1010) and a left-justified data format case (SAP output mode 0111).

Figure 2–3. Four-Channel TDM Serial Data Formats

A 16-bit field contained in the 32-bit word located at I²C subaddress 0xF9 configures both the input and output serial audio ports. Figure 2–4 illustrates the format of this 16-bit field. The data is shown in the transmitted I²C protocol format, and thus, in addition to the data, the start bit S, the slave address, the subaddress, and the acknowledges required by every byte are also shown.

Figure 2–4. SAP Configuration Subaddress Fields

Commands to reconfigure the SAP cannot be issued as standalone commands, but must accompany mute and unmute commands. The reason for this is that an SAP configuration change while a volume or bass or treble update is taking place can cause the update to not properly be completed. Figure 2–5 shows the recommended procedure for issuing SAP configuration update commands.

After a reset, ensure that 0xF9 is written before volume, treble, or bass.

Figure 2-5. Recommended Procedure for Issuing SAP Configuration Updates

Figure 2-6, Figure 2-7, and Figure 2-8 tabularize the formatting and word size options available for the input SAP and output SAP. In these figures, data formats are paired when the only difference between the pair is whether the word placement within the LRCLK period is left justified or I²S. The TDM formats available include single chip TDM output formats (SDOUT1_{chipA} or SDOUT1_{chipB}) and two chip TDM output formats (SDOUT1_{chipA} OR'ed with SDOUT1_{chipB}). For two chip TDM output formats, the OR'ing operation is accomplished by routing SDOUT1 from one of the two TAS3103 chips to ORIN of the other TAS3103 chip. The AB bit also comes into play for two chip TDM formats; AB must be set to 1 on one of the two TAS3103 chips and set to 0 on the other TAS3103 chip. For a given connection of SDOUT1 to ORIN, it does not matter which TAS3103 is set up as chip AB = 1 and which chip is set up as chip AB = 0. However, the routing of the processed data to the output registers in the TAS3103 is dependent on which chip is chip AB = 0 and which chip is chip AB = 1. Figure 2-10 and Figure 2-11 illustrate this dependence.

In Figure 2–10 and Figure 2–11, the paired TDM output formats 0101 and 1000 are unique in that each format, in effect, services two distinct industry formats. For these two modes, if register Y in chip AB = 1 is set to zero (by appropriate output mixer coefficient settings), the resulting format is a standard 8 CH TDM format. This option is illustrated in Figure 2–7.

INPUT TYPE	IM[3:0]	FORMAT	WORDSIZE	DATA DISTRIBUTION: A, B, C, D, E, F, G, H = INPUT MIXER INPUTS		
				SDIN1	SDIN2	SDIN3
DISCRETE	000X(1)	Left justified	All options valid			
	0010	Right justified	All options valid		Not available	Not available
	0011	I2S	All options valid except 32 bit		Not available	Not available
TIME DIVISION MULTIPLEX (TDM)	0100	16-bit packed	IW[2:0] = 001		Not available	Not available
	0101	8 CH transfer, left justified	All options valid		Not available	Not available
	1000	8 CH transfer, I2S	All options valid except 32 bit		Not available	Not available
	0110/1101 (2/3)	6 CH, left justified	All options valid		Not available	Not available
	1001(3)	6 CH, I2S	All options valid except 32 bit		Not available	Not available
	0111	4 CH, left justified	All options valid		Not available	Not available
	1010	4 CH, I2S	All options valid except 32 bit		Not available	Not available
	1011/1111(4)	6 CH, 20 bit	IW[2:0] = 011		Not available	Not available
	1100	6 CH data, 8 CH transfer, left justified	All options valid		Not available	Not available
	1110	6 CH data, 8 CH transfer, I2S	All options valid except 32 bit		Not available	Not available

NOTES: 1. Left justified, stereo is the default input format.

2. IM[3:0] modes 0110 and 1101 are identical for the input SAP. OM[3:0] modes 0110 and 1101 do produce different results in the output SAP (see Figure 2-7).

3. If a 6 CH input format is selected, the output format must also be set to 6 CH. When in a 6 CH mode, data format selections—I2S and left justified—for the 6 CH input SAP can be made independent of the data format selections—I2S and left justified—made for the 6 CH output SAP.

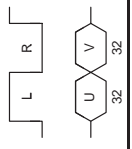

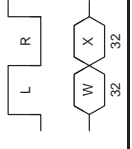

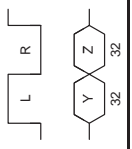

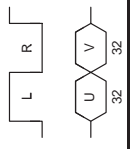

4. IM[3:0] modes 1011 and 1111 are identical for the input SAP. OM[3:0] modes 1011 and 1111 do produce different results in the output SAP (see Figure 2-7).

Figure 2-6. Format Options: Input Serial Audio Port

OUTPUT TYPE	OM[3:0]	FORMAT	WORDSIZE	DATA DISTRIBUTION: U, V, W, X, Y, Z = OUTPUT MIXER OUTPUTS		
				SDOUT1	SDOUT2	SDOUT3

(32)	1	1	1	1	1	1

DEFAULT →
 (32) ⇒ Reserved for future family members. Selection of 000, 110, or 111 in the TAS3103 selects a 32-bit sample size.

Figure 2–9. Word Size Settings

Figure 2–10. 8 CH TDM Format Using SAP Modes 0101 and 1000

Figure 2–11. 6 CH Data, 8 CH Transfer TDM Format Using SAP Modes 0101 and 1000

For these same two modes, if register X in chip AB = 0 is set to zero, and registers V and X in chip AB = 1 are set to zero, the resulting format is a 6 CH data, 8 CH transfer format. This option is shown in Figure 2–11.

The data output format in Figure 2–11 is identical to that realized using data output formats 1100 and 1110 in Figure 2–7. The difference is that SAP modes 1010 and 1000 provide six independent monaural channels to process the data, whereas SAP modes 1100 and 1110 provide only three independent monaural channels to process the data.

2.1.2 Processing Flow—SAP Input to SAP Output

All SAP data format options other than I²S result in a two-sample delay from input to output, as illustrated in Figure 2–12. Figure 2–12 is also relevant if I²S formatting is used for both the input SAP and the output SAP (the polarity of LRCLK in Figure 2–12 has to be inverted in this case). However, if I²S format conversions are performed between input and output, the delay becomes either 1.5 samples or 2.5 samples, depending on the processing clock frequency selected for the digital audio processor (DAP) relative to the sample rate of the incoming data. The input to output delay for an I²S input format and a non-I²S output format is illustrated in Figure 2–13(a), and Figure 2–13(b) illustrates the delay for a non-I²S input format and an I²S output format. In each case, two distinct input to output delay times are shown: a 1.5 sample delay time if the processing time in the DAP is less than half the sample period, and a 2.5 sample delay time if the processing time in the DAP is greater than half the sample period.

The departure from the two-sample input to output processing delay when I²S format conversions are performed is due to the use of a common LRCLK. The I²S format uses the falling edge of LRCLK to begin a sample period, whereas all other formats use the rising edge of LRCLK to begin a sample period. This means that the input SAP and digital audio processor (DAP) operate on sample windows that are 180° out of phase with respect to the sample window used by the output SAP. This phase difference results in the output SAP outputting a new data sample at the midpoint of the sample period used by the DAP to process the data. If the processing cycle completes all processing tasks before the midpoint of the processing sample period, the output SAP outputs this processed data. However, if the processing time extends past the midpoint of the processing sample period, the output SAP outputs the data processed during the previous processing sample period. In the former case, the delay from input to output is 1.5 samples. In the latter case, the delay from input to output is 2.5 samples.

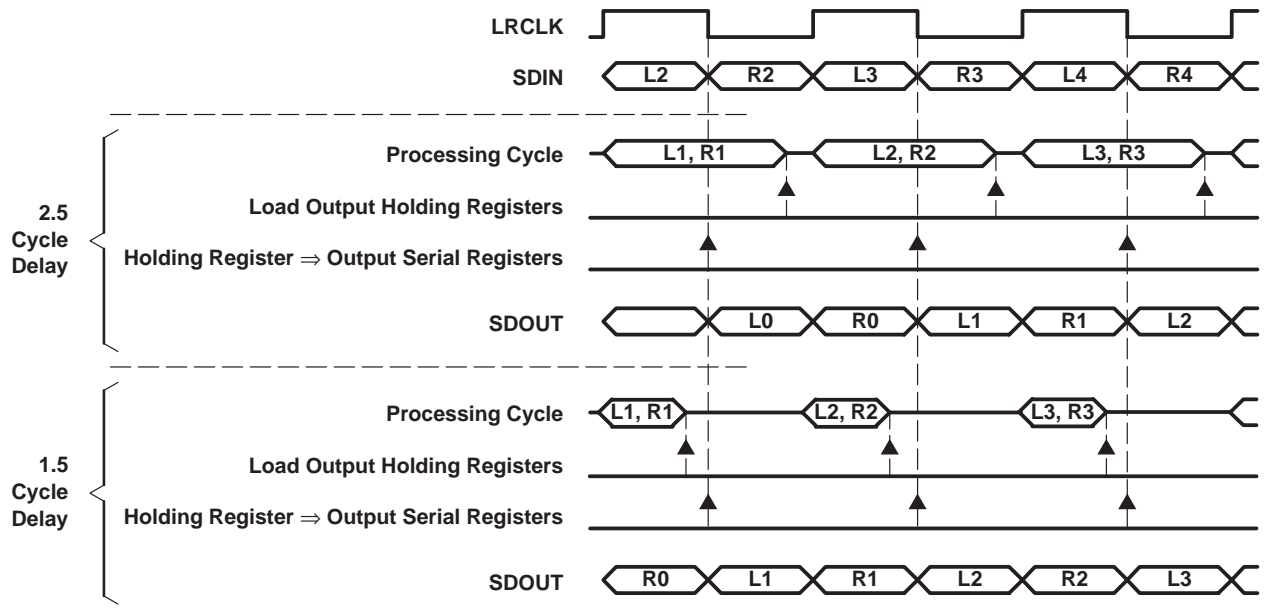

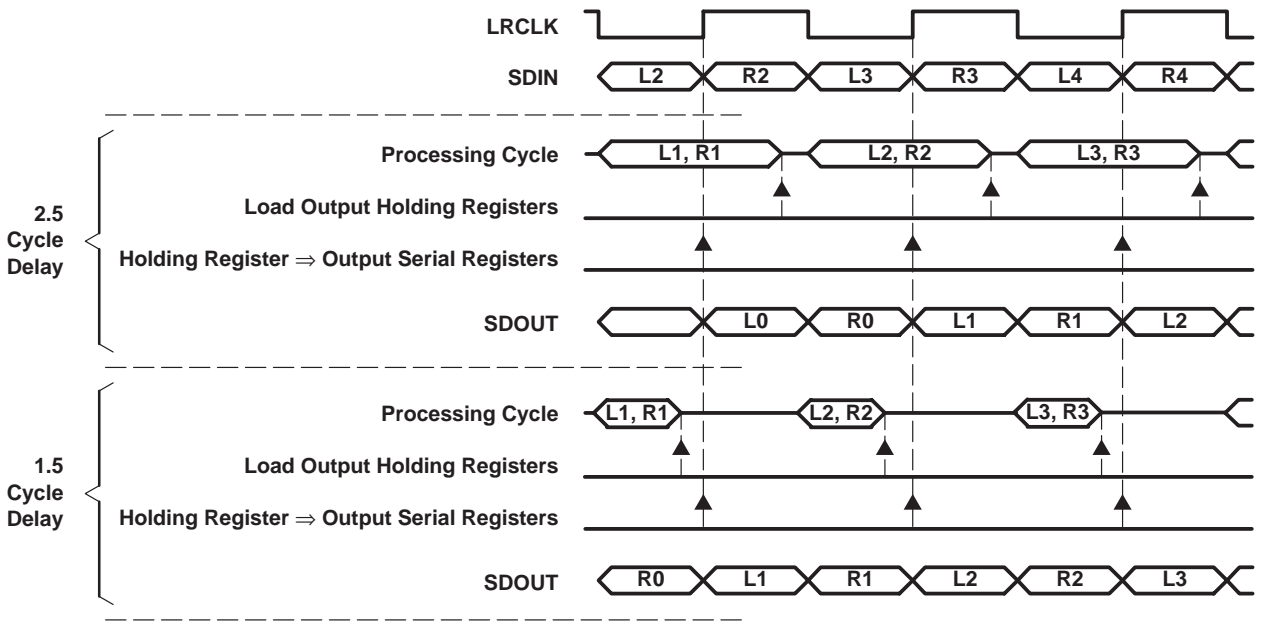

Figure 2-12. SAP Input-to-Output Latency

(a) Left-Justified Input / I²S Output

(b) I²S Input / Left-Justified Output

Figure 2–13. SAP Input-to-Output Latency for I²S Format Conversions

The delay from input to output can thus be either 1.5 or 2.5 sample times when data format conversions are performed that involves the I²S format. However, which delay time is obtained for a particular application is determinable and fixed for that application, providing care is taken in the selection of MCLKI/XTALI with respect to the incoming sample clock LRCLK.

Table 2–1 lists all viable clock selections for a given audio sample rate (LRCLK). The table only includes those clock choices that allow enough processing throughput to accomplish all tasks within a given sample time ($T_S = 1/\text{LRCLK}$). For each entry in the table, the DAP processing time is given in terms of whether the time is greater than $0.5 T_S$ (resulting in an input to output delay of $2.5 T_S$), or less than $0.5 T_S$ (resulting in an input to output delay of $1.5 T_S$).

Table 2–1 is valid for both master and slave I²S modes (bit IMS at subaddress 0xF9 determines I²S master/slave selection—see the *DPLL and Clock Management* section that follows). For all applications, MCLK must be ≥ 128 LRCLK (FS). In the I²S master mode, MCLK, SCLK (I²S bit clock) LRCLK are all harmonically related. Furthermore, in the I²S master mode, if a master clock value given in Table 2–1 is used, the latency realized in performing I²S format conversions, 1.5 samples or 2.5 samples, is stable and fixed over the duration of operation. However, greater care must be taken for the I²S slave mode. In this mode, the device has the proper operational throughput to perform all required computations as long as MCLK is ≥ 128 LRCLK. But there is no longer the requirement that MCLK be harmonically related to SCLK and LRCLK. Values of MCLK could be chosen such that the output dithers between latencies of 1.5 and 2.5 sample times. There may be cases where part of the data stream output exhibits sample time latencies of $1.5 T_S$ and the other portion of the output data stream exhibits sample time latencies of $2.5 T_S$. To assure that such cases do not happen in the I²S slave mode, the relationships between MCLK and LRCLK given in Table 2–1 should be followed for data format conversions involving the I²S format. The MCLKI/XTALI frequencies given in Table 2–1 (if set to within $\pm 5\%$ of the nominal value shown) assure that the DAP processing time falls above $0.5 T_S$ or below $0.5 T_S$ with enough margin to assure that there is no race condition between the outputting of data and the completion of the processing tasks.

Table 2–1. TAS3103 Throughput Latencies vs MCLK and LRCLK

AUDIO SAMPLE RATE (LRCLK)	MASTER CLOCK(2) (MCLKI/XTALI)	DAP(1) CLOCK (PLL_OUTPUT)	DAP CLOCK CYCLES/LRCLK	DAP PROCESSING TIME	THROUGHPUT DELAY
96 kHz	24.576 MHz, 12.288 MHz	135.168 MHz	1408	$> T_S/2$	$2.5 T_S$
88.2 kHz	22.5792 MHz, 11.2896 MHz	124.1856 MHz	1408	$> T_S/2$	$2.5 T_S$
48 kHz	24.576 MHz, 12.288 MHz	135.168 MHz	2816	$< T_S/2$	$1.5 T_S$
	24.576 MHz, 12.288 MHz, 6.144 MHz	67.584 MHz	1408	$> T_S/2$	$2.5 T_S$
44.1 kHz	22.5792 MHz, 11.2896 MHz	124.1856 MHz	2816	$< T_S/2$	$1.5 T_S$
	22.5792 MHz, 11.2896 MHz, 5.6448 MHz	62.0928 MHz	1408	$> T_S/2$	$2.5 T_S$
32 kHz	16.384 MHz, 8.192 MHz	90.112 MHz	2816	$< T_S/2$	$1.5 T_S$
	16.384 MHz, 8.192 MHz, 4.096 MHz	45.056 MHz	1408	$> T_S/2$	$2.5 T_S$
24 kHz	24.576 MHz, 12.2858 MHz	135.168 MHz	5632	$< T_S/2$	$1.5 T_S$
	24.576 MHz, 12.2858 MHz, 6.144 MHz	67.584 MHz	2816	$< T_S/2$	$1.5 T_S$
	12.288 MHz, 6.144 MHz, 3.072 MHz	33.792 MHz	1408	$> T_S/2$	$2.5 T_S$
22.05 kHz	22.5792 MHz, 11.2896 MHz	124.1856 MHz	5632	$< T_S/2$	$1.5 T_S$
	22.5792 MHz, 11.2896 MHz, 5.6448 MHz	62.0928 MHz	2816	$< T_S/2$	$1.5 T_S$
	11.2896 MHz, 5.6448 MHz, 2.8224 MHz	31.0464 MHz	1408	$> T_S/2$	$2.5 T_S$
8 kHz	24.576 MHz, 12.288 MHz	135.168 MHz	16896	$< T_S/2$	$1.5 T_S$
	24.576 MHz, 12.288 MHz, 6.144 MHz	67.584 MHz	8448	$< T_S/2$	$1.5 T_S$
	12.288 MHz, 6.144 MHz, 3.072 MHz	33.792 MHz	4224	$< T_S/2$	$1.5 T_S$
	6.144 MHz, 3.072 MHz, 1.536 MHz	16.896 MHz	2112	$> T_S/2$	$2.5 T_S$

- NOTES: 1. DAP clock is the internal digital audio processor clock. It is equal to $11 \times \text{MCLKI/XTALI}$, $11/2 \times \text{MCLKI/XTALI}$, or $11/4 \times \text{MCLKI/XTALI}$ (as determined by a bit field in I²C subaddress 0xF9). The DAP clock must always be greater than or equal to $1400 F_S$ (LRCLK).
2. Unless in PLL bypass, MCLKI must be ≤ 20 MHz.
3. XTALI must always be ≤ 20 MHz.

2.2 DPLL and Clock Management

Clock management for the TAS3103 consists of two control structures:

- Master clock management: oversees the selection of the clock frequencies for the microprocessor, the I²C controller, and the digital audio processor (DAP). The master clock (MCLKI or XTALI) serves as the source for these clocks. In most applications, the master clock is input to an on-chip digital phase lock loop (DPLL), and the DPLL output is used to drive the microprocessor and DAP clocks. A DPLL bypass mode can also be used, in which case the master clock is used to drive the microprocessor and DAP clocks.
- Serial audio port (SAP) clock management: oversees SAP master/slave mode, the settings of SCLKOUT1 and SCLKOUT2, and the setting of LRCLK in the SAP master mode.

Figure 2–14 illustrates the clock circuitry in the TAS3103. The bold lines in Figure 2–14 highlight the default settings at power turn on, or after a reset. Inputs MCLKI and XTALI source the master clock for the TAS3103. Within the TAS3103, these two inputs are combined by an OR gate, and thus only one of these two sources can be active at any one time. The source that is not active must be set to logic 0. In normal operation, the master clock is divided by 1, 2, or 4 (as determined by the logic levels set at input pins PLL0 and PLL1) and then multiplied by 11 in frequency by the on-chip DPLL. The DPLL output (or MCLKI/XTALI if the DPLL is bypassed) is the processing clock used by the digital audio processor (DAP).

The DAP processing clock can also serve as the clock for the on-chip microprocessor, or the DAP clock can be divided by four prior to sending it to the microprocessor. The input pin MICROCLK_DIV makes this clock choice. A logic 1 input level on this pin selects the DAP clock for the microprocessor clock; a logic 0 input level on this pin selects the DAP clock/four for the microprocessor clock.

The selected microprocessor clock is also used to drive the clocks used by the I²C control block. Two parameters, N and M, define the clocks used by the I²C control block. The I²C control block sampling frequency is set by $1/2^N$, where N can range in value from 0 to 7. A $1/(1 + M)$ divisor followed by a 1/10 divisor generates the data bit clock (SCL). This driven SCL clock is only used when the I²C control block is set to master mode (input pin $\overline{I2CM_S} = 1$). The default value for the I²C parameter N depends on whether the I²C controller is in a slave mode ($\overline{I2CM_S} = 0$) or a master mode ($\overline{I2CM_S} = 1$). In the I²C master mode $N = 2$ ($2^N = 4$), which assures that a 100-kHz I²C data clock (SCL) can be generated when the digital audio processor (DAP) is running at its maximum frequency of 135 MHz. In the I²C slave mode $N = 1$ ($2^N = 2$), which assures the I²C controller an adequate over-sampling clock when the DAP is running at the minimum clock frequency required to process 8-kHz audio data (approximately 11.2 MHz). In I²C master mode, the values for M and N are fixed and cannot be changed.

Figure 2-14. DPLL and Clock Management Block Diagram

When the SAP is in the master mode, the serial audio port (SAP) uses the MCLKI/XTALI master clock to drive the serial port clocks SCLKOUT1, SCLKOUT2, and LRCLK. When the SAP is in the slave mode, LRCLK is an input and SCLKOUT2 and SCLKOUT1 are derived from SCLKIN. As shown in Figure 2-14, SCLKOUT1 clocks data into the input SAP and SCLKOUT2 clocks data from the output SAP. Two distinct clocks are required to support TDM to discrete and discrete to TDM data format conversions. Such format conversions also require that SCLKIN be the higher valued bit clock frequency. For TDM in/discrete out format conversions, SCLKIN must be equal to the input bit clock. For discrete in/TDM out format conversions, SCLKIN must be equal to the output bit clock. The frequency settings for SCLKOUT1, SCLKOUT2, and LRCLK in the SAP master mode, as well as the SAP master/slave mode selection, are all controlled by I2C commands.

Table 2-2 lists the default settings at power turn on or after a received reset.

Table 2–2. TAS3103 Clock Default Settings

CLOCK	DEFAULT SETTING
SCLKOUT1	SCLKIN
SCLKOUT2	SCLKIN
LRCLK	Input
MCLKO	MCLKI or XTALI
DAP processing clock	Set by pins PLL0 and PLL1
Microprocessor clock	Set by pin MICROCLK_DIV
I ² C sampling clock	I²C master mode Microprocessor clock/4 I²C slave mode Microprocessor clock/2
I ² C master SCL	I ² C sampling clock/90

The selections provided by the dedicated TAS3103 input pins and the programmable settings provided by I²C subaddress commands give the TAS3103 a wealth of clocking options. Table 2–1, in the section describing the serial audio port (SAP), lists typical clocking selections for different audio sampling rates. However, the following clocking restrictions must be adhered to:

- MCLKI or XTALI $\geq 128 F_S$ (NOTE: For some TDM modes, MCLKI or XTALI must be $\geq 256 F_S$)
- DAP clock $\geq 1400 \times F_S$
- DAP clock < 136 MHz
- Microprocessor clock/20 \geq I²C SCL clock
- Microprocessor clock ≤ 35 MHz
- I²C oversample clock/10 \geq I²C SCL clock
- XTALI ≤ 12.288 MHz
- MCLKI ≤ 25 MHz, unless PLL is bypassed

As long as these restrictions are met, all other clocking options are allowed.

2.3 Controller

The controller serves as the interface between the digital audio processor (DAP), the asynchronous I²C bus interface, and the four general-purpose I/O (GPIO) pins. Included in the controller block is an industry-standard 8051 microprocessor and an I²C master/slave bus controller.

2.3.1 8051 Microprocessor

The 8051 microprocessor receives and distributes I²C write data, retrieves and outputs to the I²C bus controller the required I²C read data, and participates in most processing tasks requiring multiframe processing cycles. The microprocessor also controls the flow of data into and out of the GPIO pins, which includes volume control when in the I²C master mode. The microprocessor has its own data RAM for storing intermediate values and queuing I²C commands, and a fixed program ROM. The microprocessor's program cannot be altered.

2.3.2 I²C Bus Controller

The TAS3103 has a bidirectional, two-wire, I²C-compatible interface. Both 100K-bps and 400K-bps data transfer rates are supported, and the TAS3103 controller can serve as either a master I²C device or a slave I²C device. Master/slave operation is defined by the logic level input into pin $\overline{\text{I2CM_S}}$ (logic 1 = master mode, logic 0 = slave mode).

If this input level is changed, the TAS3103 must be reset.

In the I²C master mode, data rate transfer is fixed at 100 kHz, assuming MCLKI or XTALI = 12.288 MHz, PLL0 = PLL1 = 0, and MICROCLK_DIV = 0. In the I²C slave mode, data rate transfer is determined by the master device. However, the setting of I²C parameter N at subaddress 0xFB (see the *PLL and Clock Management* section) does play a role in setting the data transfer rate. In the I²C slave mode, bit rates other than (and including) the I²C-specific 100K-bps and 400K-bps bit rates can be obtained, but N must always be set so that the over-sample clock into the I²C master/slave controller is at least a factor of 10 higher in frequency than SCL.

The I²C communication protocol for the I²C slave mode is shown in Figure 2–15.

† Bits CS1 and CS0 in the TAS3103 slave address are compared to the logic levels on pins CS0 and CS1 for address verification. This provides the ability to address up to four TAS3103 chips on the same I²C bus.

Figure 2–15. I²C Slave Mode Communication Protocol

In the slave mode, the I²C bus is used to:

- Update coefficient values and output data to those GPIO ports configured as output.
- Read status flags, input data from those GPIO ports configured as inputs and retrieve spectrum analyzer/VU meter data.

In the master mode, the I²C bus is used to download a user-specific configuration from an I²C compatible EEPROM.

In the slave mode only, specific registers and memory locations in the TAS3103 are accessible with the use of I²C subaddresses. There are 256 such I²C subaddresses. The protocol required to access a specific subaddress is presented in Figure 2–16.

As shown in Figure 2–16, a read transaction requires that the master device first issue a write transaction to give the TAS3103 the subaddress to be used in the read transaction that follows. This subaddress assignment write transaction is then followed by the read transaction. For write transactions, the subaddress is supplied in the first byte of data written, and this byte is followed by the data to be written. For write transactions, the subaddress must always be included in the data written. There cannot be a separate write transaction to supply the subaddress, as was required for read transactions. If a subaddress assignment only write transaction is followed by a second write transaction supplying the data, erroneous behavior results. The first byte in the second write transaction is interpreted by the TAS3103 as another subaddress replacing the one previously written.

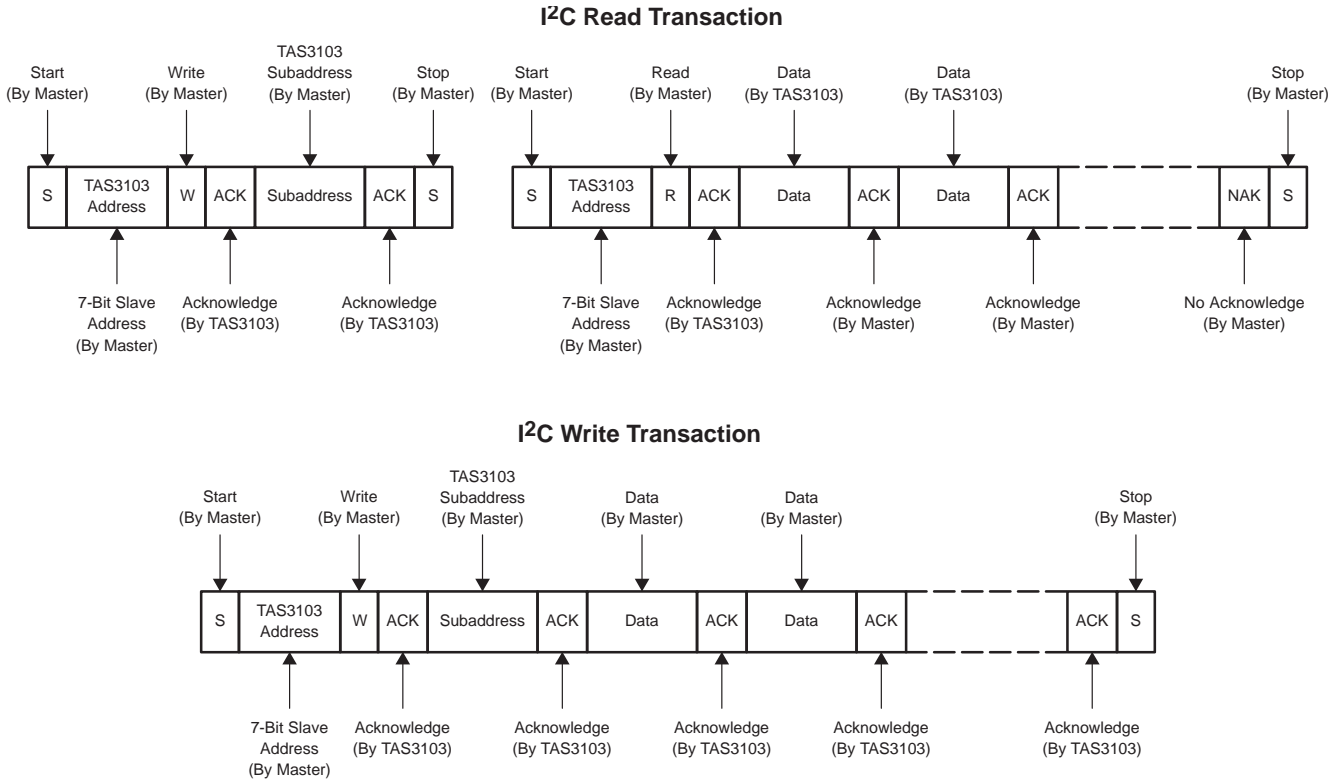

Figure 2–16. I²C Subaddress Access Protocol

2.3.2.1 I²C Master Mode Operation

The TAS3103 uses the master mode to download an operational configuration. The configuration downloaded must contain data for all 256 subaddresses, with spacer data supplied for those subaddresses that are GPIO subaddresses, read-only subaddresses, factory-test subaddresses, or unused (reserved) subaddresses. The spacer data must always be assigned the value zero. Table 2–3 organizes the 256 subaddresses (and their corresponding EEPROM addresses) into sequential blocks, with each block containing either valid data or spacer data.

Table 2–3 also illustrates that the subaddresses and their corresponding EEPROM memory addresses do not directly correlate. This is because many subaddresses are assigned more than one 32-bit word. For example, there is a unique subaddress for each biquad filter in the TAS3103, but each subaddress is assigned five 32-bit coefficients—resulting in 20 bytes of memory being assigned to each biquad subaddress.

The TAS3103, in the I²C master mode, can execute a complete download without requiring any wait states. After the TAS3103 has downloaded all 2367 bytes of coefficient and spacer data, the I²C bus is disabled and cannot be used to update coefficient values or retrieve status or spectrum/VU meter data. Volume control is available in the master mode via the four GPIO pins.

In I²C master mode, the watchdog timer must not be enabled.

When programming the EEPROM, make sure that the starting I²C check word (subaddress 0x00) and ending I²C check word (subaddress 0xFC) are identical.

Table 2–3. I²C EEPROM Data

DATA TYPE		EEPROM BYTE ADDRESSES	SUBADDRESS(es)
Valid data	Starting I ² C check word—must match ending check word	0x000–0x003	0x00
	Input mixers—set 1	0x004–0x0CF	0x01–0x33
	Effects block biquads	0x0D0–0x2AF	0x34–0x4B
	Reverb block mixers	0x2B0–0x2C7	0x4C–0x4E
	CH1 biquads	0x2C8–0x3B7	0x4F–0x5A
	CH2 biquads	0x3B8–0x4A7	0x5B–0x66
	CH3 biquads	0x4A8–0x597	0x67–0x72
	Bass and treble inline/bypass mixers	0x590–0x5AF	0x73–0x75
	DRC mixers	0x5B0–0x5DF	0x76–0x7E
	Dither input mixers	0x5E0–0x5EB	0x7F–0x81
	CH3 (sub-woofer) to CH 1/2 (L/R) mixers	0x5EC–0x5F3	0x82–0x83
	Spectrum analyzer/VU meter mixers	0x5F4–0x60B	0x84–0x89
	Output mixers	0x60C–0x66B	0x8A–0xA1
	CH1 loudness parameters	0x66C–0x697	0xA2–0xA6
	CH2 loudness parameters	0x698–0x6C3	0xA7–0xAB
	CH3 loudness parameters	0x6C4–0x6EF	0xAC–0xB0
	CH 1/2 DRC parameters	0x6F0–0x733	0xB1–0xB5
	CH3 DRC parameters	0x734–0x777	0xB6–0xBA
	Spectrum analyzer parameters	0x778–0x847	0xBB–0xC5
	Dither output mixers	0x848–0x84F	0xC6
Dither speed	0x850–0x853	0xC7	
Factory Test Data (EEPROM Spacer Data) – Zeros		0x854–0x85F	0xC8–0xC9
Valid data	Input mixers—set 2	0x860–0x87F	0xCA–0xD1
Spacer Data		0x880–0x8E3	0xD2–0xEA
Valid data	Watchdog timer enable—must be disabled = 00 00 00 01	0x8E4–0x8E7	0xEB
Factory Test Data (EEPROM Spacer Data) – Zeros		0x8E8–0x8EF	0xEC–0xED
Valid data	GPIO port parameters	0x8F0–0x8F7	0xEE–0xEF
	Volume parameters	0x8F8–0x90B	0xF0–0xF4
	Bass/treble filter selections	0x90C–0x91R	0xF5–0xF8
	I ² S command word	0x91C–0x91F	0xF9
	Delay/reverb settings	0x920–0x92B	0xFA
	I ² C M and N	0x92C–0x92F	0xFB
	Ending I ² C check word—must match starting check word	0x930–0x933	0xFC
Read Only Data (EEPROM Spacer Data)		0x934–0x941	0xFD–0xFF

NOTE: EEPROM organization must be big Endian—MS byte of data word allocated to the lowest address in memory.

The I²C master mode also utilizes the starting and ending I²C check words to verify a proper EEPROM download. The first 32-bit data word received from the EEPROM, the starting I²C check word at subaddress 0x00, is stored and compared against the 32-bit data word received for subaddress 0xFC, the ending I²C check word. These two data words must be equal as stored in the EEPROM. If the two words do not match when compared in the TAS3103, the TAS3103 conducts another parameter download from the EEPROM. If the comparison check again fails, the TAS3103 discards all downloaded parameters and set all parameters to the default values listed in the subaddress table presented in the Appendix. In the I²C slave mode, these default values are used to initialize the TAS3103 at power turnon or after a reset.

2.3.2.2 I²C Slave Mode Operation

The I²C slave mode is the mode that must be used if it is required to change configuration parameters (other than volume via the GPIO pins for the I²C master mode) during operation. The I²C slave mode is also the only I²C mode that provides access to the spectrum analyzer and VU meter outputs. Configuration downloads from a master device can be used to replace the I²C master mode EEPROM download.

For I²C read commands, the TAS3103 responds with data, a byte at a time, starting at the subaddress assigned, as long as the master device continues to respond with acknowledges. If a given subaddress does not use all 32 bits, the unused bits are read as logic 0. I²C write commands, however, are treated in accordance with the data assignment for that address space. If a write command is received for a biquad subaddress, the TAS3103 expects to see five 32-bit words. If fewer than five data words have been received when a stop command (or another start command) is received, the data received is discarded. If a write command is received for a mixer coefficient, the TAS3103 expects to see only one 32-bit word.

Supplying a subaddress for each subaddress transaction is referred to as random I²C addressing. The TAS3103 also supports sequential I²C addressing. For write transactions, if a subaddress is issued followed by data for that subaddress and the fifteen subaddresses that follow, a sequential I²C write transaction has taken place, and the data for all 16 subaddresses is successfully received by the TAS3103. For I²C sequential write transactions, the subaddress then serves as the start address and the amount of data subsequently transmitted, before a stop or start is transmitted, determines how many subaddresses are written to. As was true for random addressing, sequential addressing requires that a complete set of data be transmitted. If only a partial set of data is written to the last subaddress, the data for the last subaddress is discarded. However, all other data written is accepted; just the incomplete data is discarded.

The GPIO subaddresses and most reserved read-only and factory test subaddresses require the downloading of four bytes of zero-valued spacer data in order to proceed to the next subaddress. However, there are five exceptions to this rule and Table 2–4 lists the subaddresses of these exceptions and the number of zero-valued bytes that must be written.

Table 2–4. Four Byte Write Exceptions—Reserved and Factory-Test I²C Subaddresses

SUB-ADDRESS	NUMBER OF ZERO-VALUED BYTES THAT MUST BE WRITTEN
0xC9	8
0xED	8
0xFD	10 (0xA)
0xFE	2
0xFF	1

The TAS3103 can always receive sequential I²C addressing write data without issuing wait states. If it is desired to download data to all subaddresses using one sequential write transaction, spacer data for the reserved, GPIO, read-only, and factory-test subaddresses must be supplied as per Table 2–3 and Table 2–4.

The TAS3103 also supports sequential read transactions. When an I²C subaddress assignment write transaction is followed by a read transaction, the TAS3103 outputs the data for that subaddress, and then continue to output data for the subaddresses that follow as long as the master continues to issue data received acknowledges. Except for two exceptions, the TAS3103 outputs four bytes of zero-valued data for reserved and factory-test subaddresses. The subaddresses of the exceptions and the number of bytes supplied by the TAS3103 for each exception are given in Table 2–5. If a GPIO port is assigned as an output port, a logic 0 bit value is supplied by the TAS3103 for this GPIO port in response to a read transaction at subaddress 0xEE.

CAUTION: Sequential write transactions must be in ascending subaddress order. The TAS3103 does not wrap around from subaddress 0xFF to 0x00.

Sequential read transactions wrap around from subaddress 0xFF to 0x00.

Table 2–5. Four Byte Read Exceptions—Reserved and Factory-Test I²C Subaddresses

SUB-ADDRESS	NUMBER BYTES SUPPLIED BY TAS3103
0xC9	8
0xED	8

NOTE: Table 2–5 does not include read-only subaddresses and thus does not include subaddresses 0xFD, 0xFE, and 0xFF. When read, these read-only subaddresses output 10, 2, and 1 byte respectively.

Thus, for all reserved and factory-test subaddresses, except subaddresses 0xC9 and 0xED, the master device must issue four data received acknowledges for the four bytes of zero-valued data. For subaddresses 0xC9 and 0xED, the master device must issue eight data received acknowledges for the eight bytes of zero-valued data.

Sequential read transactions do not have restrictions on outputting only complete subaddress data sets. If the master does not issue enough data received acknowledges to receive all the data for a given subaddress, the master device simply does not receive all the data. If the master device issues more data received acknowledges than required to receive the data for a given subaddress, the master device simply receives complete or partial sets of data, depending on how many data received acknowledges are issued from the subaddress(es) that follow.

I²C read transactions, both sequential and random, can impose wait states. For the standard I²C mode (SCL = 100 kHz), worst-case wait state times for an 8-MHz microprocessor clock is on the order of 2 μ s. Nominal wait state times for the same 8-MHz microprocessor clock is on the order of 1 μ s. For the fast I²C mode (SCL = 400 kHz) and the same 8-MHz microprocessor clock, worst-case wait state times can extend up to 10.5 μ s in duration. Nominal wait state times for this same case lie in a range from 2 μ s to 4.6 μ s. Increasing the microprocessor clock frequency lowers the wait state times and for the standard I²C mode, a higher microprocessor clock can totally eliminate the presence of wait states. For example, increasing the microprocessor clock to 16 MHz results in no wait states. For the fast I²C mode, higher microprocessor clocks shortens the wait state times encountered, but does not totally eliminate their presence.

2.4 Digital Audio Processor (DAP) Arithmetic Unit

The digital audio processor (DAP) arithmetic unit is a fixed-point computational engine consisting of an arithmetic unit and data and coefficient memory blocks. Figure 2–17 is a block diagram of the arithmetic unit.

Figure 2–17. Digital Audio Processor Arithmetic Unit Block Diagram

The DAP arithmetic unit is used to implement all firmware functions—soft volume, loudness compensation, bass and treble processing, dynamic range control, channel filtering, 3D effects, input and output mixing, spectrum analyzer, VU meter, and dither.

Figure 2–18 shows the data word structure of the DAP arithmetic unit. Eight bits of overhead or guard bits are provided at the upper end of the 48-bit DAP word and 8 bits of computational precision or noise bits are provided at the lower end of the 48-bit word. The incoming digital audio words are all positioned with the most significant bit abutting the 8-bit overhead/guard boundary. The sign bit in bit 39 indicates that all incoming audio samples are treated as signed data samples.

CAUTION: Audio data into the TAS3103 is always treated as signed data.

Figure 2-18. DAP Arithmetic Unit Data Word Structure

The arithmetic engine is a 48-bit (25.23 format) processor consisting of a general-purpose 76-bit arithmetic logic unit and function-specific arithmetic blocks. Multiply operations (excluding the function-specific arithmetic blocks) always involve 48-bit DAP words and 28-bit coefficients (usually I²C programmable coefficients). If a group of products are to be added together, the 76-bit product of each multiplication is applied to a 76-bit adder, where a DSP-like multiply-accumulate (MAC) operation takes place. Biquad filter computations use the MAC operation to maintain precision in the intermediate computational stages.

To maximize the linear range of the 76-bit ALU, saturation logic is not used. Intermediate overflows are then permitted in multiply-accumulate operations, but it is assumed that subsequent terms in the multiply-accumulate computation flow corrects the overflow condition. The biquad filter structure used in the TAS3103 is the direct form I structure and has only one accumulation node. With this type of structure, intermediate overflow is allowed as long as the designer of the filters has assured that the final output is bounded and does not overflow. Figure 2-19 shows a bounded computation that experiences intermediate overflow condition. 8-bit arithmetic is used for ease of illustration.

The DAP memory banks include a dual port data RAM for storing intermediate results, a coefficient RAM, a 4K x 16 RAM for implementing the delay stages, and a fixed program ROM. Only the coefficient RAM, assessable via the I²C bus, is available to the user.

Figure 2-19. DAP ALU Operation With Intermediate Overflow

The DAP processing clock is set by pins PLL0 and PLL1, in conjunction with the source clock XTALI or MCLKI. The DAP operates at speeds up to 136 MHz, which is sufficient to process 96-kHz audio.

2.5 Reset

The reset circuitry in the TAS3103 is shown in Figure 2–20. A reset is initiated by inputting logic 0 on the reset pin $\overline{\text{RST}}$. A reset is also issued at power turnon by the internal 1.8-V regulator subsystem.

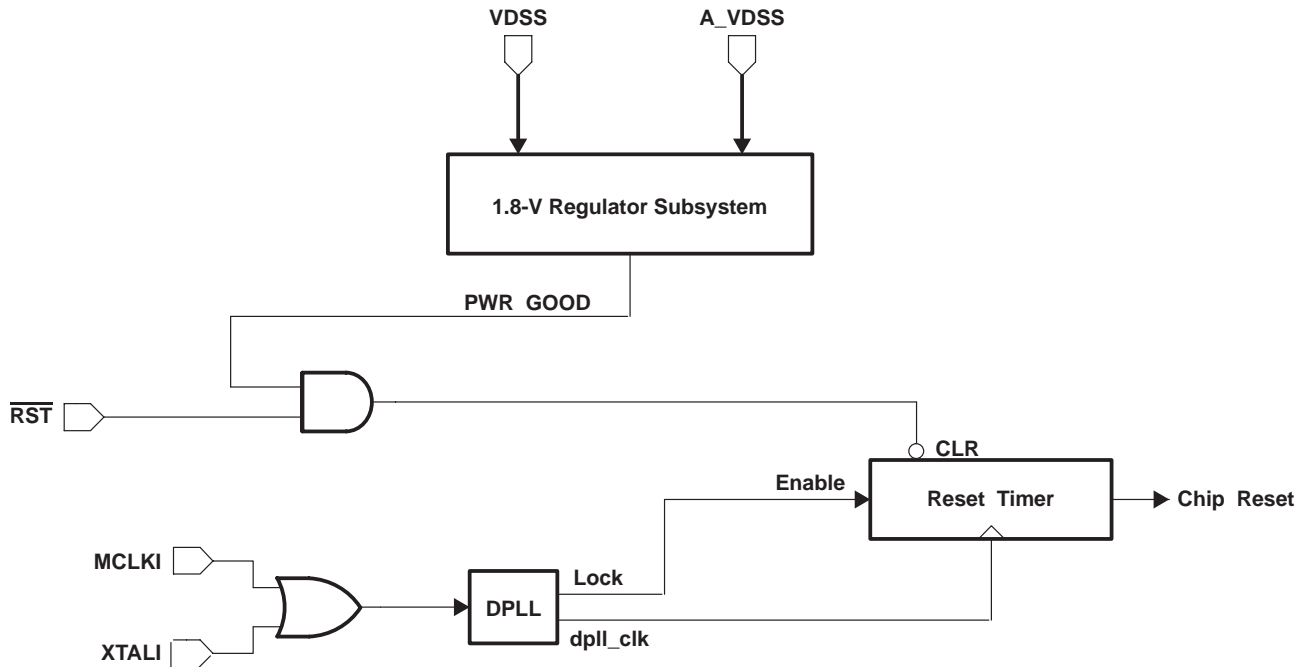

Figure 2–20. TAS3103 Reset Circuitry

At power turnon, the internal 1.8-V regulator subsystem issues an internal reset that remains active until regulation is reached. The duration of this signal assures that all reset activities are conducted at power turnon. This means that the external reset pin $\overline{\text{RST}}$ does not require an RC time constant derived external reset to assure that a reset is applied at power turnon. The reset pin $\overline{\text{RST}}$ can then be used exclusively for exception resets, saving the cost and size impact of additional RC components. However, since $\overline{\text{RST}}$ is an asynchronous clear, it can respond to narrow negative signal transitions. Some applications, therefore, might require a high-frequency capacitor on the $\overline{\text{RST}}$ pin in order to remove unwanted noise excursions.

2.6 Power Down

Setting the PWRDN pin to logic 1 enables power down. Power down stops all clocks in the TAS3103, but preserves the state of the TAS3103. When PWRDN is deactivated (set to logic 0) after a period of activation, the TAS3103 resumes the processing of audio data upon receiving the next LRCLK (indicating a new sample of audio data is available for processing). The configuration of the TAS3103 and all programmable parameters are retained during power down.

There is a time lag between setting PWRDN to logic 1 and entering the power down state. PWRDN is sampled every GPIOFSCOUNT LRCLK periods (see the *subaddress 0xEF and the watchdog timer and GPIO ports* sections). This means that a time lag as great as $\text{GPIOFSCOUNT}(1/\text{LRCLK})$ could exist between the activation of PWRDN (setting to logic 1) and the time at which the microprocessor recognizes that the PWRDN pin has been activated. Normally, upon recognizing that the PWRDN pin has been activated, the TAS3103 enters the power-down state approximately 80 microprocessor clock cycles later. However, if a soft volume update is in progress, the TAS3103 waits until the soft volume update is complete before entering the power down state. For this case then, the worst case time lag

between recognizing the activation of pin PWRDN and entering the power down would be 4096 LRCLK periods, assuming a volume slew rate selection (bit VSC of I²C subaddress 0xF1) of 4096 and the issuance of a volume update immediately preceding the reading of pin PWRDN. The worst case time lag between setting PWRDN to logic 1 and entering the power down state is then:

$$\text{power - down - time lag}_{\text{Worst-Case}} = \frac{4096 + \text{GPIOFSCOUNT}}{\text{LRCLK}} + \frac{80}{\text{Microprocessor-Clock}}$$

There is also a time lag between deactivating PWRDN (setting PWRDN to logic 0) and exiting the power down state. This time lag is set by the time it takes the internal digital PLL to stabilize, and this time, in turn, is set by the master clock frequency (MCLKI or XTALI) and the PLL output clock frequency. For a 135-MHz PLL output clock and a 24.576 MCLKI, the time lag is approximately 25 μs. For a 11.264-MHz PLL output clock and a 1.024-MHz MCLKI, the time lag is approximately 360 μs.

Power consumption in the power-down state is approximately 12 mW.

2.7 Watchdog Timer

There is a watchdog timer in the TAS3103 that monitors the microprocessor activity. If the microprocessor ever ceases to execute its stored program, the watchdog timer fires and resets the TAS3103. This capability was included in the TAS3103 for factory test purposes and has little use in applications. The program structure used in the microprocessor assures that the microprocessor always executes its stored program unless a hardware failure occurs.

The watchdog timer is governed by the parameter GPIOFSCOUNT in subaddress 0xEF and the LSB of the 32-bit word at subaddress 0xEB. The default value of the LSB of the 32-bit word at subaddress 0xEB is 1 and this value disables the watchdog timer. The GPIOFSCOUNT is also used in other functions and balancing the needs of these other functions regarding GPIOFSCOUNT with the requirements of the watchdog timer is an involved process. For this reason, it is strongly recommended that the LSB of the 32-bit word at subaddress 0xEB remain a 1. If an application does require use of the watchdog timer, it is requested that the user contact an application engineer in the Digital Audio Department of Texas Instruments for details in properly using this feature.

2.8 General-Purpose I/O (GPIO) Ports

The TAS3103 has four general-purpose I/O (GPIO) ports. Figure 2–21 is a block diagram of the GPIO circuitry in the TAS3103.

Figure 2-21. GPIO Port Circuitry

2.8.1 GPIO Functionality—I²C Master Mode

In the I²C master mode, the GPIO ports are strictly input ports and are used to control volume. Table 2-6 lists the functionality of each GPIO port in the I²C master mode. Bit field GPIOFSCOUNT (15:8) of I²C subaddress 0xEF governs the rate at which the GPIO pins are sampled for a volume update. The sample rate is:

$$f_{\text{GPIO_Port}} = \frac{\text{LRCLK}}{\text{GPIOFSCOUNT}}$$

Table 2-6. GPIO Port Functionality—I²C Master Mode

GPIO PORT	FUNCTION
GPIO0 (pin 18)	Volume up—CH1 and CH2
GPIO1 (pin 19)	Volume down—CH1 and CH2
GPIO2 (pin 20)	Volume up—CH3
GPIO3 (pin 21)	Volume down—CH3

GPIOFSCOUNT also governs the rate at which the power down pin PWRDN is sampled and the rate at which the watchdog counter is reset. GPIOFSCOUNT then cannot be independently used to tune the volume adjustment. For this reason, bit field GPIO_samp_int of the same I²C subaddress (0xEF) is included to provide the ability to adjust the responsiveness (or sluggishness) of the volume switches.

Each GPIO port has a weak pullup to VDD5. A volume control switch then typically switches the signal line to the GPIO port between ground and an open circuit. The parameter GPIO_samp_int sets how many consecutive GPIO port

samples must be logic 0 before a logic 0 is read. A read logic 0 on a given GPIO port is interpreted as a command to increase or decrease volume. If a logic 0 is read, and the signal level into the GPIO port remains at logic 0 for another GPIO_samp_int consecutive samples, a second logic 0 value is read.

For each logic 0 read, the volume is increased or decreased 0.5 dB. After two consecutive logic 0 readings, each logic 0 reading that follows results in the volume level increasing or decreasing 5 dB instead of 0.5 dB. Figure 2–22 shows an example of activating a volume switch. For the example in Figure 2–22, GPIOFSCOUNT is set to 3 and GPIO_samp_int is set to 2. It is also noted in Figure 2–22 that the parameter GPIO_samp_int only comes into play on logic 0 valued samples. As soon as the GPIO sample goes to logic 1, the audio updating ceases.

2.8.2 GPIO Functionality—I²C Slave Mode

In the I²C slave mode, the GPIO ports can be used as true general-purpose ports. Each port can be individually programmed, via the I²C bus, to be either an input or an output port. The default assignment for all GPIO ports, in the I²C slave mode, is an input port.

When a given GPIO port is programmed as an output port, by setting the appropriate bit in the bit field GPIODIR (19:16) of subaddress 0xEF to logic 1, the logic level output is set by the logic level programmed into the appropriate bit in bit field GPIO_in_out (3:0) of subaddress 0xEE. The I²C bus then controls the logic output level for those GPIO ports assigned as output ports.

When a given GPIO port is programmed as an input port by setting the appropriate bit in bit field GPIODIR (19:16) of subaddress 0xEF to logic 0, the logic input level into the GPIO port is written to the appropriate bit in bit field GPIO_in_out (3:0) of subaddress 0xEE. The I²C bus can then be used to read bit field GPIO_in_out to determine the logic levels at the input GPIO ports. Whether a given bit in the bit field GPIO_in_out is a bit to be read via the I²C bus or a bit to be written to via the I²C bus is strictly determined by the corresponding bit setting in bit field GPIODIR.

In the I²C slave mode, the GPIO input ports are read every GPIOFSCOUNT LRCLKs, as was the case in the I²C master mode. However, parameter GPIO_samp_int does not have a role in the I²C slave mode. If a GPIO port is assigned as an output port, a logic 0 bit value is supplied by the TAS3103 for this GPIO port in response to a read transaction at subaddress 0xEE.

If the GPIO ports are left in their power turnon state default state, they are input ports with a weak pullup on the input to VDSS.

Figure 2-22. Volume Adjustment Timing—Master I²C Mode

3 Firmware Architecture

3.1 I²C Coefficient Number Formats

The firmware for the TAS3103 is housed in ROM resources within the TAS3103 and cannot be altered. However, mixer gain, level offset, and filter tap coefficients, which can be entered via the I²C bus interface, provide a user with the flexibility to set the TAS3103 to a configuration that achieves the system level goals.

The firmware is executed in a 48-bit signed fixed-point arithmetic machine. The most significant bit of the 48-bit data path is a sign bit, and the 47 lower bits are data bits. Mixer gain operations are implemented by multiplying a 48-bit signed data value by a 28-bit signed gain coefficient. The 76-bit signed output product is then truncated to a signed 48-bit number. Level offset operations are implemented by adding a 48-bit signed offset coefficient to a 48-bit signed data value. In most cases, if the addition results in overflowing the 48-bit signed number format, saturation logic is used. This means that if the summation results in a positive number that is greater than 0x7FFF_FFFF_FFFF (the spaces are used to ease the reading of the hexadecimal number), the number is set to 0x7FFF_FFFF_FFFF. If the summation results in a negative number that is less than 0x8000_0000_0000 0000, the number is set to 0x8000_0000_0000 0000. There are exceptions to the use of saturation logic for summations that overflow—see the section Digital Audio Processor (DAP) Arithmetic Unit.

3.1.1 28-Bit 5.23 Number Format

All mixer gain coefficients are 28-bit coefficients using a 5.23 number format. Numbers formatted as 5.23 numbers means that there are 5 bits to the left of the decimal point and 23 bits to the right of the decimal point. This is shown in the Figure 3–1.

Figure 3–1. 5.23 Format

The decimal value of a 5.23 format number can be found by following the weighting shown in Figure 3–2. If the most significant bit is logic 0, the number is a positive number, and the weighting shown yields the correct number. If the most significant bit is a logic 1, then the number is a negative number. In this case every bit must be inverted, a 1 added to the result, and then the weighting shown in Figure 3–2 applied to obtain the magnitude of the negative number.

$$(1 \text{ or } 0) \times 2^3 + (1 \text{ or } 0) \times 2^2 + \dots + (1 \text{ or } 0) \times 2^0 + (1 \text{ or } 0) \times 2^{-1} + \dots + (1 \text{ or } 0) \times 2^{-4} + \dots + (1 \text{ or } 0) \times 2^{-23}$$

Figure 3–2. Conversion Weighting Factors—5.23 Format to Floating Point

Gain coefficients, entered via the I²C bus, must be entered as 32-bit binary numbers. The format of the 32-bit number (4-byte or 8-digit hexadecimal number) is shown in Figure 3–3.

Figure 3–3. Alignment of 5.23 Coefficient in 32-Bit I²C Word

As Figure 3–3 shows, the hex value of the integer part of the gain coefficient cannot be concatenated with the hex value of the fractional part of the gain coefficient to form the 32-bit I²C coefficient. The reason is that the 28-bit coefficient contains 5 bits of integer, and thus the integer part of the coefficient occupies all of one hex digit and the most significant bit of the second hex digit. In the same way, the fractional part occupies the lower 3 bits of the second hex digit, and then occupies the other five hex digits (with the eighth digit being the zero-valued most significant hex digit).

3.1.2 48-Bit 25.23 Number Format

All level adjustment and threshold coefficients are 48-bit coefficients using a 25.23 number format. Numbers formatted as 25.23 numbers means that there are 25 bits to the left of the decimal point and 23 bits to the right of the decimal point. This is shown in Figure 3–4.

Figure 3–4. 25.23 Format

Figure 3–5 shows the derivation of the decimal value of a 48-bit 25.23 format number.

$$\begin{array}{cccccc}
 2^{23} \text{ Bit} & & 2^{22} \text{ Bit} & & 2^0 \text{ Bit} & & 2^{-1} \text{ Bit} & & 2^{-23} \text{ Bit} \\
 \downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
 (1 \text{ or } 0) \times 2^{23} + (1 \text{ or } 0) \times 2^{22} + \dots + (1 \text{ or } 0) \times 2^0 + (1 \text{ or } 0) \times 2^{-1} + \dots + (1 \text{ or } 0) \times 2^{-23}
 \end{array}$$

Figure 3–5. Alignment of 5.23 Coefficient in 32-Bit I²C Word

Two 32-bit words must be sent over the I²C bus to download a level or threshold coefficient into the TAS3103. The alignment of the 48-bit, 25.23 formatted coefficient in the 8-byte (two 32-bit words) I²C word is shown in Figure 3–6.

Figure 3–6. Alignment of 25.23 Coefficient in Two 32-Bit I²C Words

3.2 Input Crossbar Mixers

The TAS3103 has four serial input ports—SDIN1, SDIN2, SDIN3 and SDIN4. SDIN1, SDIN2, and SDIN3 provide the input resources to process 5.1 channel audio in two TAS3103 chips. SDIN4 provides the capability to multiplex between a full 5.1 channel system and a stereo source or an *information/warning* audio message as might be found in an automotive application.

Each serial input port is assigned two internal processing nodes. The mixers following these internal processing nodes serve to distribute the input audio data to various processing nodes within the TAS3103. Figure 3–7 shows the assignment of the internal processing nodes to the serial input ports. Two cases are shown in Figure 3–7—discrete mode and TDM mode.

The input crossbar mixer topology for internal processing nodes A, B, C, D, E and F is shown in Figure 3–8. Each of the six nodes is assigned six mixers. These six mixers provide the ability to route the incoming serial port data on SDIN1, SDIN2, and SDIN3 to:

- Processing node d—bypassing effects block and directly feeding monaural CH1
- Processing node e—bypassing effects block and directly feeding monaural CH2
- Processing node f—directly feeding the section of the effects block assigned to monaural CH3
- Processing nodes a and b—directly feeding paths that contain the reverb delay elements assigned to CH1 and CH2
- Processing node c—directly feeding an effects block path assigned to CH1 and CH2 that bypasses all reverb delay elements.

The ability to route all input nodes to the same set of processing nodes fully decouples the input order (what audio components are wired to which serial input ports) from the processing flow. As is seen in the discussion of the output crossbar mixers, the output serial ports are fully decoupled from the three monaural channels (any monaural channel output can be routed to either the left or the right side of any output port). The TAS3103 thus provides full flexibility in the routing of audio data into and out of the chip.

The mixer topology for internal processing nodes g and h is shown in Figure 3–9. Nodes g and h are each assigned three mixers. The mixers provide the ability to route the incoming data on serial port SDIN4 to:

- Output processing nodes to facilitate input to output pass through
- CH1/CH2 effects block input nodes that bypass reverb delay
- CH3 effects block input node

Figure 3-7. Serial Input Port to Processing Node Topology

Figure 3-8. Input Mixer and Effects Block Topology—Internal Processing Nodes A, B, C, D, E, and F

† Monaural channels consist of 12 biquad filters, followed by bass and treble processing, followed by volume and loudness processing, followed by dynamic range control, followed by filter processing. See the TAS3103 Firmware Block Diagram in the Appendix.

Figure 3-9. Input Mixer Topology—Internal Processing Nodes G and H

All input crossbar mixers use signed 5.23 format mixer gain coefficients and all are programmable via the I²C bus. The 5.23 format provides a range of gain adjustment from 2^{-23} (–138 dB) to $2^4 - 1$ (23.5 dB).

3.3 3D Effects Block

The 3D effects block, shown in Figure 3–10, performs the first suite of processing tasks conducted on the incoming serial audio data streams. The TAS3103 has three monaural channels—CH1, CH2, and CH3. CH1 and CH2 share the same effects block, as well as the same dynamic range compression block. CH 3 has its own effects block and its own dynamic range compression block. In typical two TAS3103 chip configurations for processing 5.1 audio, monaural channels CH1 and CH2 are used to process left/right front and left/right surround audio components, and CH3 is used to process the subwoofer and center audio components. To support such a processing structure, the effects block for CH1/CH2 offers more option for inserting audio effects into the audio data stream than does the effects block for CH3.

3.3.1 CH1/CH2 Effects Block

This block consists of five signal flow paths, starting at processing nodes a, b, c, g, and h. All five paths contain four programmable biquad filters, and paths a and b contain reverb delay lines as well. Nodes a, b and c can be sourced by any of the input nodes A, B, C, D, E, and F (SDIN1, SDIN2, SDIN3). Nodes g and h can be sourced by input nodes G and H respectively (SDIN4) and/or by weighted replicas of the data on nodes A and B respectively. Nodes g and h can also be sourced by the same weighted replica of the data on node f. Node c can also be sourced by weighted replicas of the data on both node a and node b.

3D effects processing typically consist of installing sound direction effects. Sound direction effects are typically created by the use of three major components.

- Time differentiation
- Loudness differentiation
- Spectral differentiation

Time differentiation is achieved by using the paths containing the reverb delay elements. Loudness differentiation is achieved both by the mixers feeding the five paths and the two mixers located at the output of each of the five paths. Spectral differentiation is achieved using the four biquad filters located in each path.

3.3.2 CH3 Effects Block

This block, starting at node f, typically processes center and sub-woofer audio components. Time and spectral differentiation with respect of CH1 and CH2 can be realized via the reverb delay line and the four biquad filters. Loudness differentiation can be achieved by adjusting the volume level of CH3. Weighted replicas of the effects block output for CH1 and CH2 can also be summed into the output of the CH3 effects block. This capability is typically used when processing the center channel audio component.

Figure 3-10. TAS3103 3D Effects Processing Block

3.4 Biquad Filters

There are a total of 73 biquad filters in the TAS3103. The breakout of the biquad filters per functional element is given in Table 3-1.

Table 3-1. Biquad Filter Breakout

FUNCTION	BIQUAD FILTERS	SUBADDRESS
3D effects block	24	0x34-0x4B
Monaural channel CH1	12	0x4F-0x5A
Monaural channel CH2	12	0x5B-0x66
Monaural channel CH3	12	0x67-0x72
Loudness processing	3	0xA6-CH1
		0xAB-CH2
		0xB0-CH3
Spectrum analyzer/VU meter	10	0xBC-0xC5

All 73 biquad filters are second order direct form I structures. A block diagram of the structure of the biquad filter is shown in Figure 3-11.

NOTE: All gain coefficients 5.23 numbers.

Biquad Filter Coefficient Subaddress Format

S	Slave Addr	Ack	Sub-Addr	Ack	m	Ack	xxxxxxx	Ack	xxxxxxx	Ack	xxxxx	l	Ack	a ₁
					0000	s	xxx	Ack	xxxxxxx	Ack	xxxxx	s	Ack	a ₂
					m									
					0000	s	xxx	Ack	xxxxxxx	Ack	xxxxx	s	Ack	b ₀
					m									
					0000	s	xxx	Ack	xxxxxxx	Ack	xxxxx	s	Ack	b ₁
					m									
					0000	s	xxx	Ack	xxxxxxx	Ack	xxxxx	s	Ack	b ₂
					m									

NOTE: Each Biquad filter has one subaddress which contains the mixer gain coefficients a₁, a₂, b₀, b₁, b₂

Figure 3-11. Biquad Filter Structure and Coefficient Subaddress Format

The transfer function for the biquad filter is given by:

$$\frac{V_{OUT}(z)}{V_{IN}(z)} = \frac{b_0 + b_1z^{-1} + b_2z^{-2}}{1 - a_1z^{-1} - a_2z^{-2}}$$

The direct form I structure provides a separate delay element and mixer (gain coefficient) for each node in the biquad filter. Each mixer output is a signed 76-bit product of a signed 48-bit data sample (25.23 format number) and a signed 28-bit coefficient (5.23 format number). A 76-bit ALU in the TAS3103 allows the 76-bit resolution to be retained when summing the mixer outputs (filter products). This is an important factor as it removes the need to carefully tailor the order of addition for each filter implementation to minimize the effects of finite-precision arithmetic. Intermediate overflows are allowed while summing the biquad terms to further minimize the effects of finite-precision arithmetic (see the *Digital Audio Processor – DAP – Arithmetic Unit* section for more discussion on intermediate overflow).

3.5 Bass and Treble Processing

The TAS3103 has three fully independent bass and treble adjustment blocks—one for each of the three monaural channels. Adjustments in bass and treble are accomplished by selecting a bass filter set and a treble filter set, and then selecting a shelf filter within each filter set. The filter set selected, of which there are five sets for treble and five sets for bass to select from, determines the frequency at which the bass and treble adjustments take effect. The shelf filters determine the gain to be applied to the bass and treble components of the incoming audio. All selections are independent of one another—any bass filter set can be combined with any treble filter set and any shelf filter can be selected in a given filter set.

Figure 3–12 shows the bass and treble selections available, their I²C subaddresses, and the data fields in each subaddress used to make the selections. Each bass filter set has 150 low pass shelving filters to choose from, with the shelves ranging from a cut (attenuation) of 18 dB to a boost (gain) of 18 dB. A shelf selection of 0 dB effectively removes bass processing. All 150 filters in a given filter set have the same 3-dB frequency, as measured from the shelf. The only difference in the 150 filters in a given bass filter set is the gain of the shelf.

Each treble filter set has 150 high-pass shelving filters to choose from, with the shelves again ranging from a cut (attenuation) of 18 dB to a boost (gain) of 18 dB. A shelf selection of 0 dB effectively removes treble processing. All 150 filters in a given filter set have the same 3-dB frequency, as measured from the shelf. The only difference in the 150 filters in a given treble filter set is the gain of the shelf.

Commands to adjust the bass and treble levels within a given filter set (by commanding the selection of different shelving filters) results in a soft adjustment to the newly commanded levels. The filters are labeled 1 through 150, with filter #1 implementing the maximum cut (18 dB) and filter #150 implementing the maximum boost (18 dB). If a command is received to change a shelf setting, the transition is made by stepping through each filter, one at a time, until the shelf filter commanded is reached. A soft transition is achieved by residing at each step (or shelf filter) for a period determined by the programmable parameter TBLC (bit field 7:0 of subaddress 0xF1). The time period set by TBLC is TBLC/FS (where FS is the audio sample rate). For an audio sample rate of 48 kHz and a TBLC setting of 64, the dwell time on each shelf filter is approximately 1.33 ms. The transition time then depends on the number of shelves separating the current and commanded shelf values. For 48-kHz audio and a TBLC setting of 64, a maximum transition time of approximately 198 ms is required to transition from shelf #1 to shelf #150 and a minimum time of approximately 1.33 ms is required to transition from shelf x to shelf $x + 1$.

FS (LRCLK)	3-dB CORNERS (kHz)									
	FILTER SET 5		FILTER SET 4		FILTER SET 3		FILTER SET 2		FILTER SET 1	
	BASS	TREBLE	BASS	TREBLE	BASS	TREBLE	BASS	TREBLE	BASS	TREBLE
96 kHz	0.25	6	0.5	12	0.75	18	1	24	1.5	36
88.4 kHz	0.23	5.525	0.46	11.05	0.691	16.575	0.921	22.1	1.381	33.15
64 kHz	0.167	4	0.333	8	0.5	12	0.667	16	1	24

44.1 kHz	0.115	2.756	0.23	5.513	0.345	8.269	0.459	11.025	0.689	16.538
38 kHz	0.099	2.375	0.198	4.75	0.297	7.125	0.396	9.5	0.594	14.25
32 kHz	0.083	2	0.167	4	0.25	6	0.333	8	0.5	12
24 kHz	0.063	1.5	0.125	3	0.188	4.5	0.25	6	0.375	9
22.05 kHz	0.057	1.378	0.115	2.756	0.172	4.134	0.23	5.513	0.345	8.269
16 kHz	0.042	1	0.083	2	0.125	3	0.167	4	0.25	6
12 kHz	0.031	0.75	0.063	1.5	0.094	2.25	0.125	3	0.188	4.5
11.025 kHz	0.029	0.689	0.057	1.378	0.086	2.067	0.115	2.756	0.172	4.134

Figure 3-12. Bass and Treble Filter Selections

CAUTION: There is no soft transition implemented when changing bass and treble filter sets; soft transitions only apply when adjusting gains (shelves) within a given filter set. The variable TBLC should be set so that the dwell time at each shelf is never less than 32 audio sample periods; otherwise audio artifacts could be introduced into the audio data stream.

Figure 3–12 summarizes the bass and treble adjustments available within each monaural channel. As noted in Figure 3–12, the 3-dB frequency for the bass filter sets decreases in value as the filter set number is increased, whereas the 3-dB frequency for the treble filter set increases in value as the filter set number is increased. The valid selection for bass and treble sets ranges from 1 to 5.

Table 3–2 and Table 3–3 list, respectively, the bass and treble filter shelf selections for all 1/2 dB settings between 18-dB cut and 18-dB boost. The treble and bass selections are not the same, and the delta in the selection values between 1/2 dB points are not constant across the 36-dB range. Table 3–2 and Table 3–3 do not list all 150 filter shelf selections, but all 150 selection values for both bass and treble are valid, allowing the use of linear potentiometer or GUI-based sliders. Table 3–2 and Table 3–3 are provided for those applications requiring the adjustment of bass and treble in 1/2 dB steps.

CAUTION: Filter set selections 6 and 7 are illegal. Filter shelf selections 0 and 151 through 255 are illegal. Programming an illegal value could result in erratic and erroneous behavior.

As an example, consider the case of a 44.1-kHz audio sample rate. For this audio rate it is desired to have, for all three monaural channels

- A 3-dB bass shelf corner frequency of 100 Hz
- A bass shelf volume boost of 9 dB
- A 3-dB treble shelf corner frequency of 8.1 kHz
- A treble shelf volume cut of 4 dB

Bass and treble filter set selections can be made by referring to Figure 3–12. For a 44.1-kHz audio sample rate, filter set 5 provides a 3-dB bass corner frequency at 115 Hz, and filter set 3 provides a 3-dB treble corner frequency at 8.269 kHz. These corner frequencies are the closest realizable corner frequencies to the specified 100-Hz bass and 8.1-kHz treble corner frequencies.

Table 3–2 provides the indices for achieving specified bass volume levels. An index of 0x55 yields a bass shelf gain of 9 dB, which matches the specified shelf volume boost of 9 dB. Table 3–3 provides the indices for achieving specified treble volume levels. An index of 0x7A yields a treble shelf cut of 4 dB (–4-dB gain), which matches the specified shelf volume cut of 4 dB.

Figure 3–13 presents the resulting subaddress entries required to implement the parameters specified in the bass and treble example.

Figure 3–13. Bass and Treble Application Example—Subaddress Parameters

3.5.1 Treble and Bass Processing and Concurrent I²C Read Transactions

I²C read transactions at subaddresses 0x01 through 0xD1 are not allowed during: (1) transitions between filter shelves within a given bass or treble filter set or (2) transitions between filter sets. This means that after issuing an I²C command to change treble or bass filter shelves or filter sets, time must be allowed to complete the bass/treble activity before proceeding to read subaddresses 0x01 through 0xD1. There is no subaddress available to directly monitor bass/treble activity. However, there is a means of probing the state of bass/treble activity via the *factory test* subaddresses 0xEC and 0xED.

If it is required to read subaddress data that falls in the subaddress range of 0x01 through 0xD1 after issuing an I²C command to change treble or bass filter shelves or filter sets, the procedure presented in Figure 3–14 can be used to monitor bass/treble activity. As Figure 3–14 shows, six readings must be taken to verify that none of the three monaural channels have on-going bass or treble activity. If all six readings show the value zero in the 8th or least significant byte of the 8-byte data word output at subaddress 0xED, then all commanded bass/treble activity has completed and it is safe to resume I²C read transactions at subaddresses 0x01 through 0xD1.

Figure 3-14. I2C Bass/Treble Activity Monitor Procedure

3.6 Soft Volume/Loudness Processing

Each of the three monaural channels in the TAS3103 has dedicated soft volume control and loudness compensation. Volume level changes are issued by I²C bus commands in the I²C slave mode and by setting the appropriate GPIO pin to logic 0 in the I²C master mode. Commanded changes in volume are implemented softly, using a smooth S-curve trajectory to transition the volume to the newly commanded level.

Volume commands are formatted as signed 5.23 numbers. The maximum volume boost then is 24 dB (4 bits x 6 dB/bit); the maximum volume cut is ∞ with a volume command of zero. The maximum finite volume cut is 138 dB (23 bits x 6 dB/bit). The resolution of the volume adjustment is not fixed over all gain settings. For large gains the resolution of the volume adjustment is very fine, and the resolution of the volume adjustment decreases as the volume gain decreases. As an example, at maximum gain, the volume level can be adjusted to a resolution of 0.000001 dB [(138 + 24) dB adjustment range/ 2^{27} adjustment steps]. At the other end of the gain scale, if the volume setting is at the maximum finite cut (volume command = 0x0000001) and is increased by one count (volume command = 0x0000002), a 6-dB adjustment is realized.

Each monaural channel volume control is also assigned a separate mute command, which has the same effect as issuing a zero-valued volume command. If loudness is enabled, disabling it by setting the parameter G to zero is necessary to obtain a total cut ($-\infty$ dB). This requirement is further discussed in the paragraphs that follow.

Loudness compensation tracks the volume control setting to allow spectral compensation. An example of loudness compensation would be a boost in bass frequencies to compensate for weak perceived bass at low volume levels. Both linear and log control laws can be implemented for volume gain tracking, and a dedicated biquad filter can be used to achieve spectral discernment.

3.6.1 Soft Volume

Figure 3–15 is a simplified block diagram of the implementation of soft volume and loudness compensation. A volume level change (either via an I²C bus issued command in the I²C slave mode, or a GPIO-issued command in the I²C master mode) initiates a transition process that assures a smooth transition to the newly commanded volume level without producing artifacts such as pops, clicks, and zipper noise. The transition time, or volume slew rate, can be selected to occupy a time window of either 2048 or 4096 audio sample periods. For 48-kHz audio, for example, this equates to a transition time of 42.67 ms or 85.34 ms. It is anticipated that 42.67 ms is the transition time of choice for most applications, and the 4096 sample transition option is primarily included to yield the same 42.67-ms transition time for 96-kHz audio. The slope of the S-curve (and its implementation) is proprietary and cannot be altered.

If additional volume commands for a given monaural channel are received, while a previously commanded volume change is still active, the last command received over-writes previous commands and is used. When the previously commanded transition completes, the volume command last received while the transition was taking place is acted upon and a new transition to this volume level initiated. For example, assume three volume commands are sequentially issued, via the I²C bus, to adjust the volume levels of the three monaural channels in the TAS3103. The first command received immediately triggers the start of a soft volume transition to the newly commanded level. The other two volume commands are received and queued to await the completion of the currently active soft volume transaction. When the first soft volume transition completes, and assuming no further volume commands have been received to replace the other two volume commands received, the next two volume commands are activated, and soft volume transitions on both monaural channels takes place. The total time then, for a 48-kHz audio sample rate and a transition selection of 2048 FS cycles is 2 x 42.67 ms or 85.34 ms. If, during the first soft volume transition, a second volume command is received for this same monaural channel, the second soft volume transition period would have soft volume transitions taking place on all three monaural channels. It is also noted that the soft volume transition time is independent of the magnitude of the adjustment. All volume commands take 2048 or 4096 FS cycles, regardless of the magnitude of the change.

In the I²C slave mode, the status of a commanded soft volume transition can be found by reading bit 0 of the 32-bit data word retrieved at subaddress 0xFF. If this bit is set to logic 1, one or more monaural channels are actively transitioning their volume setting. If a volume transition is taking place on one of the monaural channels in the TAS3103, volume commands received for the other two monaural channels are not acted upon until the active volume transition completes. When the active volume transition does complete, the latest volume commands received for the three monaural channels during the previous soft volume transition time are serviced.

Figure 3–15. Soft Volume and Loudness Compensation Block Diagram

Figure 3–15 is a more detailed block diagram of soft volume and loudness compensation, and includes the I²C subaddress commands that control volume and loudness compensation. Volume control is accomplished using three I²C subaddresses—volume control, mute/unmute control, and volume slew rate control.

Volume control in the TAS3103 applies a linear gain. The volume commands issued via I²C subaddresses 0xF2, 0xF3, and 0xF4 (monaural channels 1, 2, and 3 respectively) are signed 5.23 format numbers. These commands are applied to mixers, whose other input port is the audio data stream. The mixer output is the product of the audio data stream and the volume command. Examples of volume command settings are given below.

$$\text{Volume Command} = 0x3580B07 = 0011_0.101_1000_0000_1011_0000_0111 = 6.6878365$$

$$\text{Volume Command} = 0x01F0000 = 0000_0.001_1111_0000_0000_0000_0000 = 0.2421875$$

$$\text{Volume Command} = 0xCD6EFFE = 1100_1.101_0110_1110_1111_1111_1110 = -6.3208010$$

The volume control range is $0 = -\infty$ to $2^{-23} = -138.47$ dB to $2^4 - 2^{-23} = 24.08$ dB. Volume control is achieved by means of a 5.23 format gain coefficient that is applied to a linear mixer. The volume gain setting realized, for a given volume gain coefficient is:

$$\text{Gain} = 20 \log (\text{Volume_Gain_Coefficient})$$

There are several techniques of volume management for a linear volume control process.

- Precise calculations involving logarithms can be employed.
- A high-resolution gain table, with entries for every 0.5-dB step, can be employed.
- A more coarse gain table (entries in 3 to 6-dB steps with linear interpolation between entries) can be employed.
- Or approximations involving very simple calculations can be employed.

As an example of using approximations, equations for increasing a linear 5.23 gain setting X by 0.5 dB that involve only simple binary shift and add operations and the accuracy of these equations are given below.

$$20\log_{10}X + 0.5 \text{ dB} \approx X + 2^{-4}X \text{ gives } 0.52657877\text{-dB steps}$$

$$20\log_{10}X + 0.5 \text{ dB} \approx X + 2^{-4}X - 2^{-8}X \text{ gives } 0.49458651\text{-dB steps}$$

$$20\log_{10}X + 0.5 \text{ dB} \approx X + 2^{-4}X - 2^{-8}X + 2^{-11}X \text{ gives } 0.49859199\text{-dB steps}$$

$$20\log_{10}X + 0.5 \text{ dB} \approx X[1 + 2^{-4} - 2^{-8} + 2^{-11} + 2^{-12} - 2^{-13} + 2^{-14} - 2^{-16} + 2^{-18}] \text{ gives } 0.4999997332 \text{ dB-steps}$$

Approximations can also be found for decreasing a linear 5.23 gain setting X by 0.5 dB that involve using only simple binary shift and add operations, but the equations differ slightly from those used to increase the gain in 0.5-dB steps. The approximations to decrease the volume by 0.5 dB and the accuracy of these approximations are given below.

$$20\log_{10}X - 0.5 \text{ dB} \approx X - 2^{-4}X \text{ gives } -0.56057447 \text{ dB-steps}$$

$$20\log_{10}X - 0.5 \text{ dB} \approx X - 2^{-4}X + 2^{-7}X \text{ gives } -0.48849199\text{-dB steps}$$

$$20\log_{10}X - 0.5 \text{ dB} \approx X - 2^{-4}X + 2^{-7}X - 2^{-10}X \text{ gives } -0.49746965\text{-dB steps}$$

$$20\log_{10}X - 0.5 \text{ dB} \approx X[1 - 2^{-4} + 2^{-7} - 2^{-10} - 2^{-12} - 2^{-15} - 2^{-21}] \text{ gives } -0.5000006792 \text{ dB-steps}$$

Repeated use of a set of the above approximations results in an accumulation of the errors in the approximations. For example, if an application started at 0-dB volume, and repeatedly used the approximations to increase and decrease the volume, the exact reference point of 0 dB would be lost. If an application does require the maintenance of accurate reference points, it is necessary for the application to establish a set of exact gain reference settings and command these exact settings in place of a computed gain setting whenever the current gain setting and the next computed gain setting straddle an exact gain setting.

Table 3–4 lists the I²C coefficient settings to adjust volume from 24 dB to –136 dB in 0.5-dB steps. For each volume

setting, the gain in dB is presented in one column, the same gain in a floating point number $\left(\text{float} = 10^{\frac{\text{Gain}_{\text{dB}}}{20}}\right)$ is presented in the adjacent column, and the same gain formatted in the 32-bit hexadecimal gain coefficient format required to enter the value into the TAS3103 via the I²C bus is presented in a third column.

3.6.1.1 Soft Volume Adjustment Range Limitations

When the 2048 sample transition time is selected for the S-curve volume transition, the full $-\infty$ to 24-dB adjustment range is available. All possible values but one in the signed 28-bit (5.23 format) volume level command range are valid volume level selections. The one exception is the maximum negative volume level command 0x08000000. This value is illegal and if used, could result in erratic behavior that requires a reset to the part to correct.

When the 4096 sample transition time is selected, the upper two bits of the 28-bit volume command cannot be used. This means that the valid volume level command range is reduced to a maximum positive value of 0x1FFFFFFF (12 dB) and a maximum negative value of 0x0E000000 (also 12 dB, but with a 180° phase inversion of the audio signal). Values above these maximum levels could result in erratic behavior that requires a reset to the part to correct. Although the volume boost for the 4096 sample transition time is limited to 12 dB, volume boost can be realized elsewhere in the processing signal flow, such as in the input crossbar mixers, the biquad filters in the three monaural channels, or the biquad filters in the effects block.

3.6.1.2 Soft Volume Transitions and Concurrent I²C Read Transactions

I²C read transactions at subaddresses 0x01 through 0xD1 are not allowed during volume level transitions, as read activity during volume level transitions could result in erroneous data being output. If it is required to read subaddress

data that falls in the subaddress range 0x01 through 0xD1 after issuing an I²C command to change the volume level on one of the three monaural channels, the *busy* bit at subaddress 0xFF must be monitored to determine when the volume activity has ceased and it is safe to resume I²C read activity at subaddresses 0x01 through 0xD1. A value of 0 in the least significant bit of the byte output upon reading subaddress 0xFF signifies that all volume transition activity has completed.

3.6.2 Loudness Compensation

Loudness compensation employs a single, coefficient-programmable, biquad filter and a function block $f(\text{volume_setting})$, whose output is only a function of the volume control setting. The biquad filter input is the channel processed audio data stream that also feeds the volume gain-control mixer. The biquad output feeds a gain control mixer whose other input is the volume control setting after processing by the function block $f(\text{volume_setting})$. Loudness compensation then allows a given spectral segment of the audio data stream (as determined by the biquad filter coefficients) to be given a delta adjustment in volume as determined by the programmable function block $f(\text{volume_setting})$.

The output of the function block $f(\text{volume_setting})$ can be expressed in terms of the programmable I²C coefficients as:

$$f(\text{volume_setting}) = [(\text{volume_setting})^{LG} \times 2^{LO} \times G] + O$$

where:

- LG = logarithmic gain = 5.23 format number
- LO = logarithmic offset = 25.23 format number
- G = gain = 5.23 format number
- O = offset = 25.23 format number

If LG = 0.5, LO = 0.0, G = 1.0, and O = 0.0, $f(\text{volume_setting})$ becomes:

$$f(\text{volume_setting}) = \sqrt{\text{volume_setting}}$$

The output of the soft volume/loudness compensation block for the above case would be:

$$\text{audio}_{\text{Out}} = [\text{audio}_{\text{In}} \times \text{volume_setting}] + [\text{audio}_{\text{In}} \times F(s)_{\text{Biquad}} \times \sqrt{\text{volume_setting}}]$$

If a given monaural channel is set up as in the above example, a true mute is not obtained when a mute command is issued for the monaural channel. A mute command results in a volume control setting of 0.0. LG and LO operate in logarithmic space and the logarithm of 0.0 is $-\infty$. Therefore $(\text{volume_setting})^{-\infty}$ and $2^{-\infty}$ should both be of value 0. However, the function block $f(\text{volume_setting})$ approximates logarithmic arithmetic and a consequence of the mathematical approximations used is that the function block can output a non-zero value for an input volume setting of 0.0. For $f(\text{volume_setting}) = \sqrt{\text{volume_setting}}$, a volume_setting value of 0.0 results in the function block outputting a gain coefficient that cuts the output of the biquad filter by approximately 90 dB. If true muting is required, it can be achieved by setting G = 0.0 after the volume control setting has softly transitioned to 0.0.

Figure 3–16. Detailed Block Diagram—Soft Volume and Loudness Compensation

If G is set to 0.0 and O is set to 0.0, loudness compensation is disabled. If G is set to 0.0 and O is set to 1.0, the biquad-filtered audio is directly added to the volume level adjusted audio. Typically, LG and LO are used to derive the desired loudness compensation function, G is used to turn loudness compensation on and off, and O is used to enable and disable the biquad filter output when automatic volume tracking is turned off.

3.6.3 Time Alignment and Reverb Delay Processing

The TAS3103 provides delay line facilities at two locations in the TAS3103—in the 3D effects block (reverb delay), and at the output mix block (delay). There are three reverb delay blocks, one for each monaural channel, and these delay elements are typically used in implementing sound spatiality, a single mix reverberation, and other sound effects. There are also three delay blocks, again one for each monaural channel, and these delay elements are typically used for temporal channel alignment. The delay line facilities are implemented using a single 4K (4096) x 16-bit RAM resource. Each delay element implemented provides a one-sample delay (1/FS). The size of each delay line can be programmed via the I²C bus, or set by the EEPROM download in the I²C master mode. The only restriction is that the total delay line resources programmed cannot exceed the capacity of the 4K x 16-bit memory bank.

Figure 3–17 illustrates how delay line structures are established within the 4K RAM memory. As seen in Figure 3–17, each delay line immediately begins where the previously implemented delay line leaves off. The actual placement of the pointers is computed by the resident microprocessor; the user need only enter the delay value required. However, the following four points must be kept in mind in programming the lengths of the delay lines.

1. Each delay line of length L requires L+1 memory sample spaces
2. Reverb delay lines require three memory words (48 bits) to implement a single delay element as the reverb delay line operates in the 48-bit word structure of the digital audio processor (DAP).
3. Delay lines require two memory words (32 bits) to implement a single delay element as the delay lines operate on the mixer outputs after 32-bit truncation has been applied,
4. There are five words of reserved memory space that must be preserved.

In Figure 3–17, the terms P_{CHx} refer to delay line size assignments for the delay lines. The terms P_{Rx} see the delay line size assignments for the reverb delay lines. For the example shown in Figure 3–17, the delay for channel 3 is set to 0 and the reverberation delay for channel 2 is set to 0. From these zero-valued settings, it is seen that a delay of 0 requires the use of one delay element. For the case of a delay of 0, the write transaction into the single delay element takes place before the read from the single delay element, thereby achieving a net delay of 0.

In making the delay line length assignments, the only restriction is that the 4K memory resource not be exceeded. Figure 3–18 illustrates the computations required to determine the maximum delay line length obtainable for five cases:

1. One reverb delay line
2. One delay line
3. Three equal length reverb delay lines but no delay lines
4. Three equal length delay lines but no reverb delay lines
5. Three equal length delay lines and three equal length reverb delay lines.

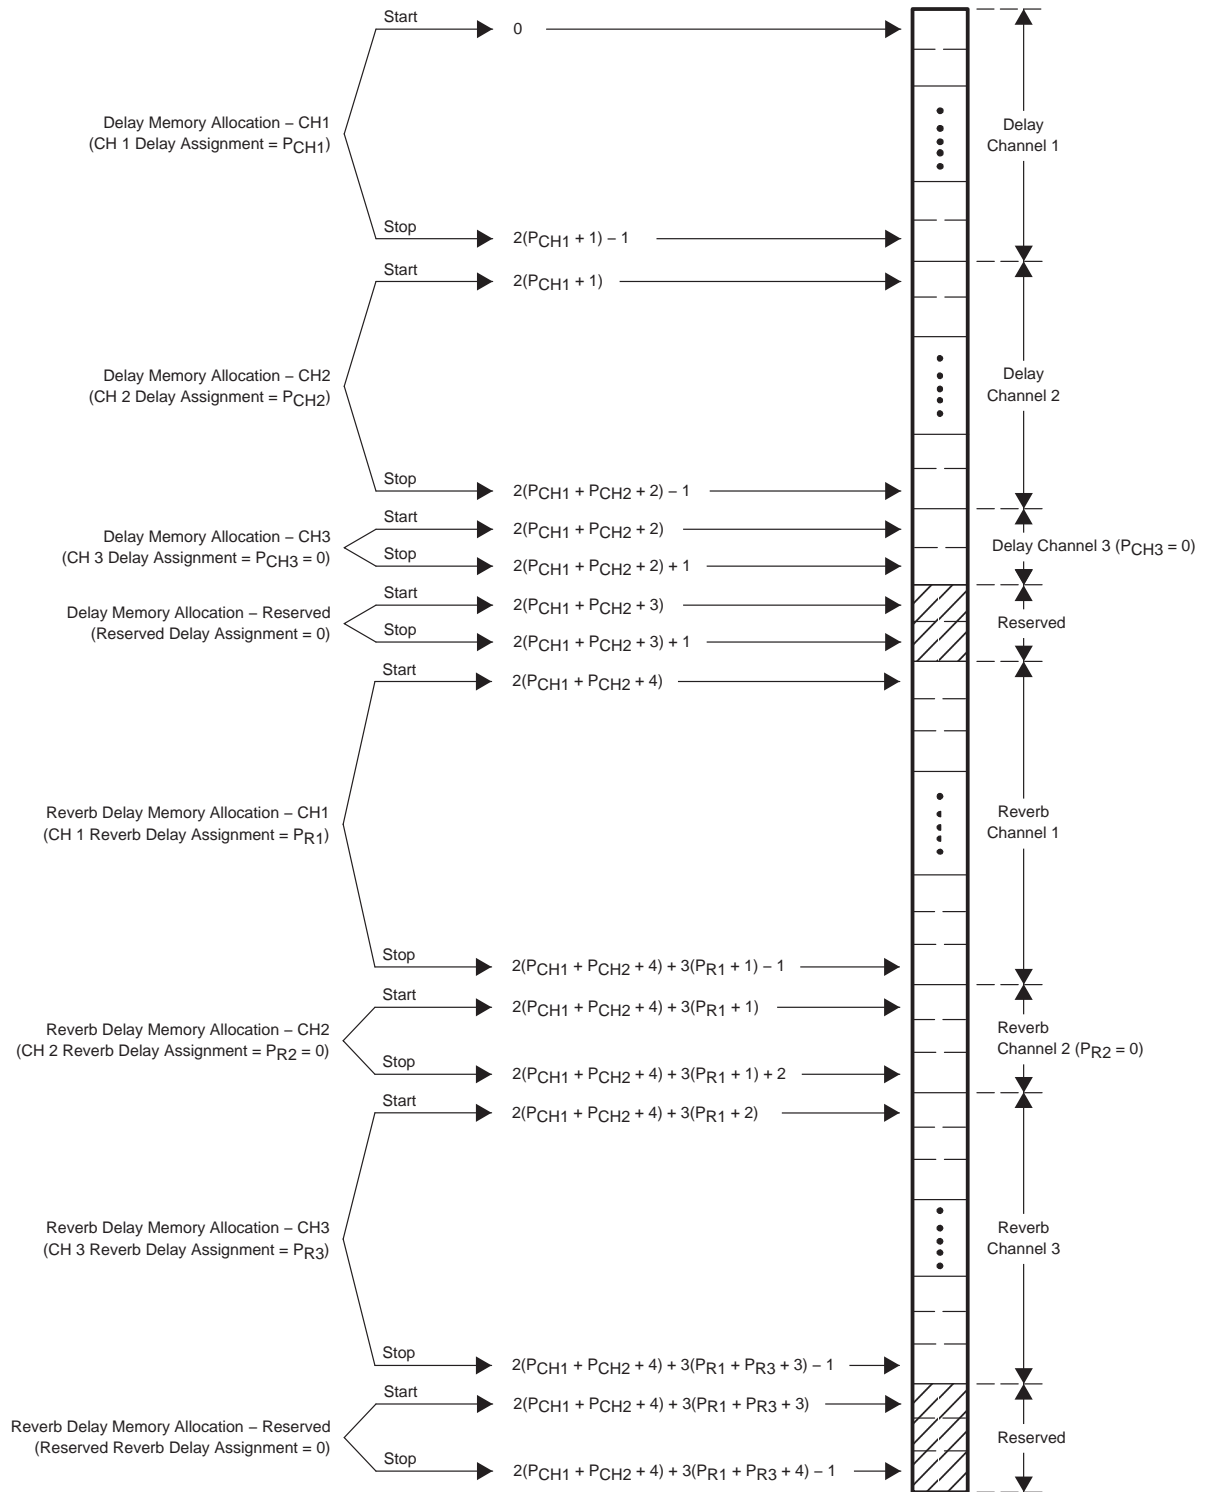

Figure 3–17. Delay Line Memory Implementation

CASE 1: Maximum Length – One Reverb Delay Line

CASE 2: Maximum Length – One Delay Line

CASE 3: Maximum Length – Three Equal Length Reverb Delay Lines

CASE 4: Maximum Length – Three Equal Length Delay Lines

CASE 5: Maximum Length – Three Equal Length Delay Lines and Three Equal Length Reverb Delay Lines

R takes $\frac{3}{2}$ the memory D does, so there should be three D elements for every two R elements.

Therefore, $D = \frac{3}{2}R$

$4091 = 3[2(\frac{3}{2}R + 1)] + 3[3(R + 1)] \rightarrow R = 226 \frac{4}{9} \rightarrow \boxed{226}$

$D = \frac{3}{2}R \rightarrow D = \boxed{339}$

Figure 3–18. Maximum Delay Line Lengths

Commands to reconfigure the reverb delay and delay lines should not be issued as standalone commands. When new delay assignments are issued, the content of the 4K memory resource used to implement the delay lines is not flushed. It takes a finite time for the memory to refill with samples in correspondence with its new assignments, and until this time has elapsed, audio samples can be output on the wrong channel. For this reason, it is recommended that all delay line assignment commands be preceded by a mute command, and followed by an unmute command.

CAUTION: There are no error flags issued if the delay line assignments exceed the capacity of the 4K memory resource, but undefined and erratic behavior results if the delay line capacity is exceeded.

3.7 Dynamic Range Control (DRC)

The DRC provides both compression and expansion capabilities over three separate and definable regions of audio signal levels. Programmable threshold levels set the boundaries of the three regions. Within each of the three regions a distinct compression or expansion transfer function can be established and the slope of each transfer function is determined by programmable parameters. The offset (boost or cut) at the two boundaries defining the three regions can also be set by programmable offset coefficients. The DRC implements the composite transfer function by computing a 5.23 format gain coefficient from each sample output from the rms estimator. This gain coefficient is then applied to a mixer element, whose other input is the audio data stream. The mixer output is the DRC-adjusted audio data.

There are two distinct DRC blocks in the TAS3103. One DRC services two monaural channels—CH1 and CH2. This DRC computes rms estimates of the audio data streams on both CH1 and CH2. The two estimates are then compared on a sample-by-sample basis, and the larger of the two is used to compute the compression/expansion gain coefficient. The gain coefficient is then applied to both CH1 and CH2 audio. The other DRC services only monaural channel CH3. This DRC also computes an rms estimate of the signal level on CH3, and this estimate is used to compute the compression/expansion gain coefficient applied to CH3 audio.

Figure 3–19 shows the positioning of the DRC block in the TAS3103 processing flow. As seen, the DRC input can come from either before or after soft volume control and loudness processing, or can be a weighted combination of both. The mixers feeding the DRC control the selection of which audio data stream or combination thereof, is input into the DRC. The mixers also provide a means of gaining or attenuating the signal level into the DRC. If the DRC setup is referenced to the 0-dB level at the TAS3103 input, the coefficient values for these mixers must be taken into account. Discussions and examples that follow further explore the role the mixers play in setting up the transfer function of the DRC.

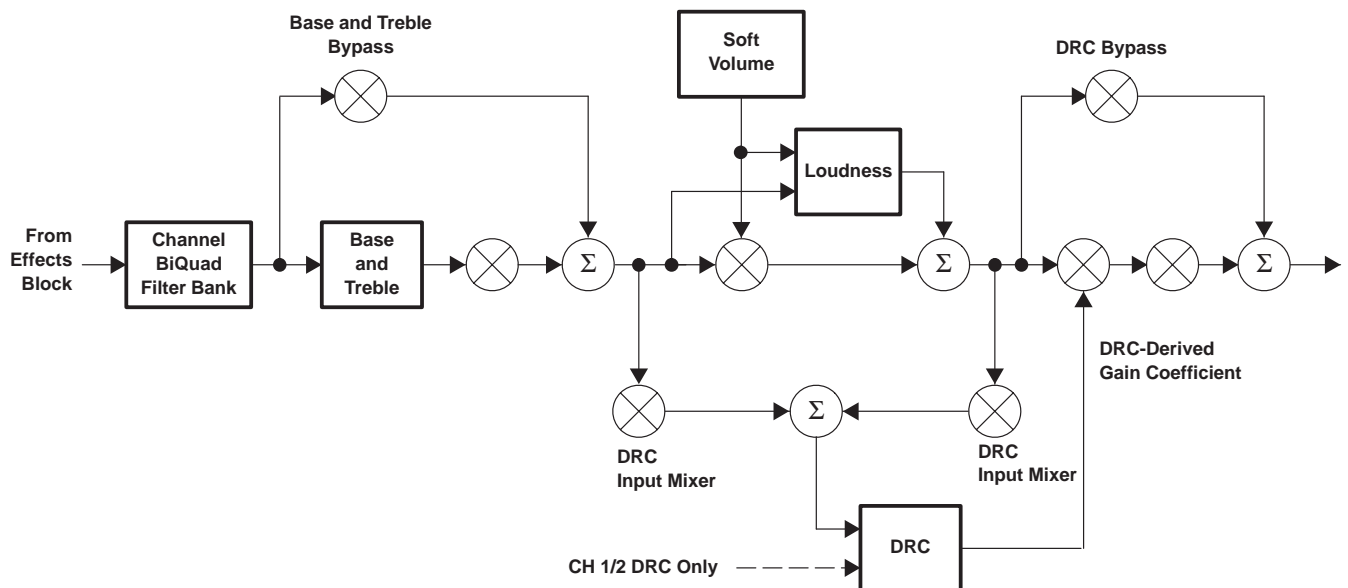

Figure 3–19. DRC Positioning in TAS3103 Processing Flow

Figure 3–20 illustrates a typical DRC transfer function.

Figure 3–20. Dynamic Range Compression (DRC) Transfer Function Structure

The three regions shown in Figure 3–20 are defined by three sets of programmable coefficients:

- Thresholds T1 and T2—define region boundaries.
- Offsets O1 and O2—define the DRC gain coefficient settings at thresholds T1 and T2 respectively.
- Slopes k0, k1, and k2—define whether compression or expansion is to be performed within a given region. The magnitudes of the slopes define the degree of compression or expansion to be performed.

The three sets of parameters are all defined in logarithmic space and adhere to the following rules:

- The maximum input sample into the DRC is referenced at 0 dB. All values below this maximum value then have negative values in logarithmic (dB) space.
- The samples input into the DRC are 32-bit words and consist of the upper 32 bits of the 48-bit word format used by the digital audio processor (DAP). The 48-bit DAP word is derived from the 32-bit serial data received at the serial audio receive port by adding 8 bits of headroom above the 32-bit word and 8 bits of computational precision below the 32-bit word. If the audio processing steps between the SAP input and the DRC input result in no accumulative boost or cut, the DRC would operate on the 8 bits of headroom and the 24 MSBs of the audio sample. Under these conditions, a 0-dB (maximum value) audio sample (0x7FFFFFFF) is seen at the DRC input as a –48-dB sample (8 bits x –6.02 dB/bit = –48 dB).
- Thresholds T1 and T2 define, in dB, the boundaries of the three regions of the DRC, as referenced to the rms value of the data into the DRC. Zero valued threshold settings reference the maximum valued rms input into the DRC and negative valued thresholds reference all other rms input levels. Positive valued thresholds have no physical meaning and are not allowed. In addition, zero valued threshold settings are not allowed.

Although the DRC input is limited to 32-bit words, the DRC itself operates using the 48-bit word format of the DAP. The 32-bit samples input into the DRC are placed in the upper 32 bits of this 48-bit word space. This means that the threshold settings must be programmed as 48-bit (25.23 format) numbers.

CAUTION: Zero valued and positive valued threshold settings are not allowed and cause unpredictable behavior if used.

- Offsets O1 and O2 define, in dB, the attenuation (cut) or gain (boost) applied by the DRC-derived gain coefficient at the threshold points T1 and T2 respectively. Positive offsets are defined as cuts, and thus boost or gain selections are negative numbers. Offsets must be programmed as 48-bit (25.23 format) numbers.
- Slopes k0, k1, and k2 define whether compression or expansion is to be performed within a given region, and the degree of compression or expansion to be applied. Slopes are programmed as 28-bit (5.23 format) numbers.

3.7.1 DRC Implementation

Figure 3–21 shows the three elements comprising the DRC: (1) an rms estimator, (2) a compression/expansion coefficient computation engine, and (3) an attack/decay controller.

- **RMS estimator**—This DRC element derives an estimate of the rms value of the audio data stream into the DRC. For the DRC block shared by CH1 and CH2, two estimates are computed—an estimate of the CH1 audio data stream into the DRC, and an estimate of the CH2 audio data stream into the DRC. The outputs of the two estimators are then compared, sample-by-sample, and the larger valued sample is forwarded to the compression/expansion coefficient computation engine.

Two programmable parameters, ae and $(1 - ae)$, set the effective time window over which the rms estimate is made. For the DRC block shared by CH1 and CH2, the programmable parameters apply to both rms estimators. The time window over which the rms estimation is computed can be determined by:

$$t_{\text{window}} = \frac{-1}{F_S \ln(1 - ae)}$$

- **Compression/expansion coefficient computation**—This DRC element converts the output of the rms estimator to a logarithmic number, determines the region that the input resides, and then computes and outputs the appropriate coefficient to the attack/decay element. Seven programmable parameters— $T1$, $T2$, $O1$, $O2$, $k0$, $k1$, and $k2$ —define the three compression/expansion regions implemented by this element.
- **Attack/decay control**—This DRC element controls the transition time of changes in the coefficient computed in the compression/expansion coefficient computation element. Four programmable parameters define the operation of this element. Parameters ad and $1 - ad$ set the decay or release time constant to be used for volume boost (expansion). Parameters aa and $1 - aa$ set the attack time constant to be used for volume cuts. The transition time constants can be determined by:

$$t_a = \frac{-1}{F_S \ln(1 - aa)} \qquad t_d = \frac{-1}{F_S \ln(1 - ad)}$$

Figure 3-21. DRC Block Diagram

3.7.2 Compression/Expansion Coefficient Computation Engine Parameters

There are seven programmable parameters assigned to each DRC block: two threshold parameters - T1 and T2, two offset parameters - O1 and O2, and three slope parameters - k0, k1, and k2. The threshold parameters establish the three regions of the DRC transfer curve, the offsets anchor the transfer curve by establishing known gain settings at the threshold levels, and the slope parameters define whether a given region is a compression or an expansion region.

The audio input stream into the DRC must pass through DRC-dedicated programmable input mixers. These mixers are provided to scale the 32-bit input into the DRC to account for the positioning of the audio data in the 48-bit DAP word and the net gain or attenuation in signal level between the SAP input and the DRC. The selection of threshold values must take the gain (attenuation) of these mixers into account. The DRC implementation examples that follow illustrate the effect these mixers have on establishing the threshold settings.

T2 establishes the boundary between the high-volume region and the mid-volume region. T1 establishes the boundary between the mid-volume region and the low-volume region. Both thresholds are set in logarithmic space, and which region is active for any given rms estimator output sample is determined by the logarithmic value of the sample.

Threshold T2 serves as the fulcrum or pivot point in the DRC transfer function. O2 defines the boost (> 0 dB) or cut (< 0 dB) implemented by the DRC-derived gain coefficient for an rms input level of T2. If O2 = 0 dB, the value of the derived gain coefficient is 1.0 (0x00, 80, 00, 00 in 5.23 format). k2 is the slope of the DRC transfer function for rms input levels above T2 and k1 is the slope of the DRC transfer function for rms input levels below T2 (and above T1). The labeling of T2 as the fulcrum stems from the fact that there cannot be a discontinuity in the transfer function at T2. The user can, however, set the DRC parameters to realize a discontinuity in the transfer function at the boundary defined by T1. If no discontinuity is desired at T1, the value for the offset term O1 must obey the following equation.

$$O1_{\text{No Discontinuity}} = |T1 - T2| \times k1 + O2 \quad \text{For } (|T1| \geq |T2|)$$

T1 and T2 are the threshold settings in dB, k1 is the slope for region 1, and O2 is the offset in dB at T2. If the user chooses to select a value of O1 that does not obey the above equation, a discontinuity at T1 is realized.

Going down in volume from T2, the slope k1 remains in effect until the input level T1 is reached. If, at this input level, the offset of the transfer function curve from the 1:1 transfer curve does not equal O1, there is a discontinuity at this input level as the transfer function is snapped to the offset called for by O1. If no discontinuity is wanted, O1 and/or k1 must be adjusted so that the value of the transfer curve at the input level T1 is offset from the 1:1 transfer curve by the value O1. The examples that follow illustrate both continuous and discontinuous transfer curves at T1.

Going down in volume from T1, starting at the offset level O1, the slope k0 defines the compression/expansion activity in the lower region of the DRC transfer curve.

3.7.2.1 Threshold Parameter Computation

For thresholds,

$$T_{\text{dB}} = -6.0206 T_{\text{INPUT}} = -6.0206 T_{\text{SUB_ADDRESS_ENTRY}}$$

If, for example, it is desired to set T1 = -64 dB, then the subaddressaddress entry required to set T1 to -64 dB is:

$$T1_{\text{SUB_ADDRESS_ENTRY}} = \frac{-64}{-6.0206} = 10.63$$

From Figure 3–21, it can be seen that T1 is entered as a 48-bit number in 25.23 format. Therefore:

$$\begin{aligned} T1 = 10.63 &= 0_1010.1010_0001_0100_0111_1010_111 \\ &= 0x00000550A3D7 \text{ in 25.23 format} \end{aligned}$$

3.7.2.2 Offset Parameter Computation

The offsets set the boost or cut applied by the DRC-derived gain coefficient at the threshold point. An equivalent statement is that offsets represent the departure of the actual transfer function from a 1:1 transfer at the threshold point. Offsets are 25.23 formatted 48-bit logarithmic numbers. They are computed by the following equation.

$$O_{\text{INPUT}} = \frac{O_{\text{DESIRED}} + 24.0824 \text{ dB}}{6.0206}$$

Gains or boosts are represented as negative numbers; cuts or attenuation are represented as positive numbers. For example, to achieve a boost of 21 dB at threshold T1, the I²C coefficient value entered for O1 must be:

$$\begin{aligned} O1_{\text{INPUT}} &= \frac{-21 \text{ dB} + 24.0824 \text{ dB}}{6.0206} = 0.51197555 \\ &= 0.1000_0011_0001_1101_0100 \\ &= 0x00000041886A \text{ in 25.23 format} \end{aligned}$$

More examples of offset computations are included in the following examples.

3.7.2.3 Slope Parameter Computation

In developing the equations used to determine the subaddress input value required to realize a given compression or expansion within a given region of the DRC, the following convention is adopted.

$$\text{DRC Transfer} = \text{Input Increase} : \text{Output Increase}$$

If the DRC realizes an output increase of n dB for every dB increase in the rms value of the audio into the DRC, a 1:n expansion is being performed. If the DRC realizes a 1 dB increase in output level for every n dB increase in the rms value of the audio into the DRC, a n:1 compression is being performed.

For 1:n expansion, the slope k can be found by:

$$k = n - 1$$

For n:1 compression, the slope k can be found by: $k = \frac{1}{n} - 1$

In both expansion (1:n) and compression (n:1), n is implied to be greater than 1. Thus, for expansion:

$k = n - 1$ means $k > 0$ for $n > 1$. Likewise, for compression, $k = \frac{1}{n} - 1$ means $-1 < k < 0$ for $n > 1$. Thus, it appears that k must always lie in the range $k > -1$.

The DRC imposes no such restriction and k can be programmed to values as negative as -15.999. To determine what results when such values of k are entered, it is first helpful to note that the compression and expansion equations for k are actually the same equation. For example, a 1:2 expansion is also a 0.5:1 compression.

$$0.5 \text{ Compression} \Rightarrow k = \frac{1}{0.5} - 1 = 1$$

$$1 : 2 \text{ Expansion} \Rightarrow k = 2 - 1 = 1$$

As can be seen, the same value for k is obtained either way. The ability to choose values of k less than -1 allows the DRC to implement negative slope transfer curves within a given region. Negative slope transfer curves are usually not associated with compression and expansion operations, but the definition of these operations can be expanded to include negative slope transfer functions. For example, if $k = -4$

$$\text{Compression Equation} : k = -4 = \frac{1}{n} - 1 \Rightarrow n = -\frac{1}{3} \Rightarrow -0.3333 : 1 \text{ compression}$$

$$\text{Expansion Equation} : k = -4 = n - 1 \Rightarrow n = -3 \Rightarrow 1 : -3 \text{ expansion}$$

With $k = -4$, the output decreases 3 dB for every 1 dB increase in the rms value of the audio into the DRC. As the input increases in volume, the output decreases in volume.

3.7.3 DRC Compression/Expansion Implementation Examples

The following four examples illustrate the steps that must be taken to calculate the DRC compression/expansion coefficients for a specified DRC transfer function. The first example is an expansion/compression/expansion implementation without discontinuities in the transfer function and represents a typical application. This first example also illustrates one of the three modes of DRC saturation—32-bit dynamic range limitation saturation. The second example is a compression/expansion/compression implementation. There is no discontinuity at T1 and 32-bit dynamic range saturation occurs at low volume levels into the DRC. Example 2 also illustrates another form of DRC saturation—maximum gain saturation. Example 3 illustrates the concept of infinite compression. Also, in Example 3, 32-bit dynamic range saturation occurs at low volume levels and the third form of DRC saturation is illustrated—minimum gain saturation. Example 4 illustrates the ability of the DRC to realize a negative slope transfer function. This example also illustrates two of the three forms of saturation—32-bit dynamic range saturation at low volume levels and minimum gain saturation.

CAUTION:

The examples presented all exhibit some form of DRC saturation. This is not intended to imply that all (or most) DRC transfer implementation exhibit some form of saturation. Most practical implementations do not exhibit saturation. The examples are chosen to explain by example the three types of saturation that can be encountered. But the phenomenon of saturation can also be used to advantage in that it effectively provides a means to implement more than three zones or regions of operation. If saturation is intended, the regions exhibiting the transfer characteristic set by k0, k1, and k2 provide three regions and the regions exhibiting saturation provide the additional regions of operation.

3.7.3.1 Example 1—Expansion/Compression/Expansion Transfer Function With 32-Bit Dynamic Range Saturation

For this example, the following transfer characteristics are chosen.

- Threshold point 2: T2 = -26 dB, O2 = 30 dB
- Threshold point 1: T1 = -101 dB, O1 = -7.5 dB
- Region 0 slope: k0 = 0.05 ≥ 1:1.05 Expansion
- Region 1 slope: k1 = -0.5 ≥ 2:1 Compression
- Region 2 slope: k2 = 0.1 ≥ 1:1.1 Expansion

The thresholds T1 and T2 are typically referenced, by the user, to the 0-dB signal level into the TAS3103. But to determine the equivalent threshold point at the DRC input, it is necessary to take into account the processing gain (or loss) between the TAS3103 SAP input and the DRC. Assume, as an example, the processing gain structure shown in Figure 3–22. Inputting the data below the 8-bit headroom in the 48-bit DAP word and then routing only the upper 32 bits of the 48-bit word into the DRC, results in a 48-dB (8 bits x 6 dB/bit = 48 dB) attenuation of the signal level into the DRC. Channel processing gain and use of the dedicated mixer into the DRC can revise this apparent 48-dB attenuation in signal level into the DRC. In Figure 3–22, the 2⁴ mixer gain into the DRC, coupled with a net channel gain of 0 dB, changes the net 48-dB attenuation of the signal level into the DRC to a net attenuation of 24 dB.

For slopes:

Region 0 = 1:1.05 Expansion	≥ k0 = 1.05 – 1 = 0.05 = 00000.0000_1100_1100_1100_1100 = 0x0066666 in 5.23 format
Region 1 = 2:1 Compression	≥ k1 = 1/2 – 1 = -0.5 = 11111.1000_0000_0000_0000_0000 = 0xFC00000 in 5.23 format
Region 2 = 1:1.1 Expansion	≥ k2 = 1.1 – 1 = 0.1 = 00000.0001_1001_1001_1001_1001 = 0x00CCCCC in 5.23 format

Figure 3-22. DRC Input Word Structure for 0-dB Channel Processing Gain

The resulting DRC transfer function for the above parameters is shown in Figure 3-23. The threshold T2 is set at the DRC rms input level of -50 dB, which corresponds to a -26 -dB rms signal level at the SAP input. The DRC-compensated output at T2 is cut 30 dB with respect to the 1:1 transfer function ($O_2 = 30$ dB). The threshold T1 is set at the DRC rms input level of -125 dB, which corresponds to a -101 -dB rms signal level at the SAP input. The DRC-compensated output at T1 is boosted by 7.5 dB with respect to the 1:1 transfer function ($O_1 = -7.5$ dB).

For thresholds, $T_{dB} = -6.0206T_{INPUT} = -6.0206T_{SUB_ADDRESS_ENTRY}$.

Therefore,

$$\begin{aligned}
 T_2 = -26 \text{ dB} - 24 \text{ dB} = -50 \text{ dB} \geq T_{2INPUT} &= -50 / -6.0206 = 8.30482 \\
 &= 01000.0100_1110_0000_1000_1010_111 \\
 &= 0x000004270457 \text{ in 25.23 format}
 \end{aligned}$$

$$\begin{aligned}
 T_1 = -101 \text{ dB} - 24 \text{ dB} = -125 \text{ dB} \geq T_{1INPUT} &= -125 / -6.0206 = 20.76205 \\
 &= 010100.1100_0011_0001_0101_1011_010 \\
 &= 0x00000A618ADA \text{ in 25/23 format}
 \end{aligned}$$

For offsets, $O_{INPUT} = \frac{1}{6.0206} [O_{dB} + 24.0824]$.

$$\begin{aligned}
 \text{Therefore, } O_{2INPUT} &= \frac{1}{6.0206} [30 + 24.0824] = 8.982892 \\
 &= 01000.1111_1011_1001_1110_1100_111 \\
 &= 0x0000047DCF67 \text{ in 25.23 format}
 \end{aligned}$$

$$\begin{aligned}
O1_{\text{INPUT}} &= \frac{1}{6.0206}[-7.5 + 24.0824] = 2.754277 \\
&= 010.1100_0001_0001_1000_0100_110 \\
&= 0x000001608C26 \text{ in } 25.23 \text{ format}
\end{aligned}$$

For input levels above the T2 threshold, the transfer function exhibits a 1:1.1 expansion. For input levels below T2, the transfer function exhibits a 2:1 compression. Also, by definition, it is seen that there is no discontinuity in the transfer function at T2. When the 2:1 compression curve in region 1 intersects the T1 threshold level, the output level is 7.5 dB above the 1:1 transfer, an offset value identical to O1. Thus, there is no discontinuity at T1. For input levels below T1, the transfer function exhibits a 1:1.05 expansion.

DRC rms input levels below -192 dB fall below the 32-bit precision of the DRC input ($32 \text{ bits} \times -6 \text{ dB/bit} = -192 \text{ dB}$). This means that for levels below -192 dB, the DRC sees a constant input level of 0, and thus the computed DRC gain coefficient remains fixed at the value computed when the input was at -192 dB. The transfer function then has a 1:1 slope below the -192 -dB input level and is offset from the 1:1 transfer curve by the offset present at the -192 -dB input level.

The change from a 1:1.05 expansion to a 1:1 transfer below -192 dB is the result of 32-bit dynamic range saturation at the DRC input. This type of saturation always occurs at a DRC input level of -192 dB. However, the input level at which this type of saturation occurs depends on the channel gain. For this example, the saturation occurs at an input level of -168 dB (-192 -dB DRC input + 48 dB 8-bit headroom -24 -dB mixer gain into DRC).

3.7.3.2 Example 2—Compression/Expansion/Compression Transfer Function With Maximum Gain Saturation and 32-Bit Dynamic Range Saturation

The transfer function parameters for this example are given in Table 3–5. In setting the threshold levels it is assumed that the net processing gain between the SAP input and the DRC is 0 dB. This is the same as Example 1 except that the gain of the mixer into the DRC is set to 1 instead of 2^4 . Because of the 8-bit headroom in the 48-bit DAP word, the upper eight bits of the 32-bit DRC input word are zero, resulting in 0-dB signal levels at the SAP input being seen as -48 -dB signal levels at the DRC.

Figure 3–23 shows the DRC transfer function resulting from the parameters given in Table 3–5. At threshold level T2 (-70 dB), O2 specifies a boost of 30 dB. But the signed 5.23 formatted gain coefficient only provides a 24-dB boost capability ($5 \text{ integer bits} = S_{xxxx} \geq 2^4 \times 6 \text{ dB/octave} = 24 \text{ dB}$). Internally, the DRC operates in 48-bit space and thus computes a 30-dB boost. But the 5.23 formatted gain coefficient saturates or clips at 24 dB. The transfer curve thus resides 24 dB above the 1:1 transfer curve at T2.

Figure 3–23. DRC Transfer Curve—Example 1

The transfer curve remains a constant 24 dB above the 1:1 transfer curve for input levels above and below T2 until the computed DRC gain coefficient falls within the dynamic range of a 5.23 format number. For input levels above T2, k2 implements a 5:1 compression. At an input level 7.5 dB above T2 (-62.5 dB), the DRC transfer curve has risen $7.5/5 = 1.5$ dB. The boost at this point is $30 \text{ dB} - (7.5 \text{ dB} - 1.5 \text{ dB}) = 24 \text{ dB}$. The DRC has come out of gain saturation. For input levels above -62.5 dB, the transfer curve exhibits 5:1 compression.

Table 3–5. DRC Example 2 Parameters

DRC PARAMETER	REQUIRED (SPECIFIED) VALUE (NET GAIN _{SAP Input-DRC} = 0 dB)	I ² C COEFFICIENT VALUE
T2	$-22 \text{ dB}_{\text{Input}} \geq -70 \text{ dB}_{\text{DRC}}$	$-70/-6.0206 = 11.626748$ = 0x000005D03948 _{25.23 Format}
T1	$-102 \text{ dB}_{\text{Input}} \geq -150 \text{ dB}_{\text{DRC}}$	$-150/-6.0206 = 24.91446$ = 0x00000C750D09 _{25.23 Format}
O2	-30 dB	$(-30 + 24.0824)/6.0206 = -0.982892$ = 0xFFFFF823098 _{25.23 Format}
O1	50 dB	$(50 + 24.0824)/6.0206 = 12.304820$ = 0x000006270458 _{25.23 Format}
k2	5:1 Compression	$(1/5) - 1 = -0.8 = 0xF99999A$ _{5.23 Format}
k1	1:2 Expansion	$2 - 1 = 1 = 0x0800000$ _{5.23 Format}
k0	2:1 Compression	$(1/2) - 1 = -0.5 = 0xFC00000$ _{5.23 Format}

For input levels below T2, k1 implements a 1:2 expansion. With a 1:2 expansion in effect, the transfer curve has dropped 12 dB at an input level 6 dB below T2. The boost at this level is $30 \text{ dB} - (12 \text{ dB} - 6 \text{ dB}) = 24 \text{ dB}$. The DRC gain coefficient has again come out of saturation. For input levels below -76 dB and above -150 dB, the transfer curve exhibits a 1:2 expansion.

At T1 (-150 dB), the transfer curve is 50 dB below the 1:1 transfer curve. Since O1 = 50 dB, there is no discontinuity in the transfer function. For inputs below -150 dB, k0 implements a 2:1 compression. The change from a 2:1 compression to a 1:1 transfer at -192 dB is due to 32-bit dynamic range saturation at the DRC input.

3.7.3.3 Example 3—1:1 Transfer/Infinite Compression With Minimum Gain Saturation, 32-Bit Dynamic Range Saturation, and Equal Threshold Settings (T1=T2)

The DRC transfer function parameters for this example are given in Table 3–6. In addition to illustrating minimum gain saturation, this example also illustrates the operation of the DRC when T1 and T2 are set equal.

Figure 3–24. DRC Transfer Curve—Example 2

When T1 and T2 are set equal, the following questions arise:

- If $O1 \neq O2$, what roles do O1 and O2 have?
- Which slope parameter, k0 or k1, has control of the transfer function for input levels below the common threshold point?
- Does k2 control the transfer function for inputs above the common threshold point?

This example addresses and answers those questions.

Table 3–6. DRC Example 3 Parameters

DRC PARAMETER	REQUIRED (SPECIFIED) VALUE (NET GAIN _{SAP Input-DRC} = 0 dB)	I ² C COEFFICIENT VALUE
T1 and T2	$-148.7 \text{ dB}_{\text{Input}} \geq -172.7 \text{ dB}_{\text{DRC}}$	$-172.7/-6.0206 = 28.684849$ = 0x00000E57A91F _{25.23} Format
O2	-20 dB	$(-20 + 24.0824)/6.0206 = 0.678072$ = 0x00000056CB0F _{25.23} Format
O1	10 dB	$(10 + 24.0824)/6.0206 = 5.660964$ = 0x000002D49A78 _{25.23} Format
k2	∞ :1 Compression	$(1/\infty) - 1 = -1 = 0xF8000000$ _{5.23} Format
k1	1:1 Transfer	$(1/1) - 1 = 0 = 0x00000000$ _{5.23} Format
k0	2:1 Compression	$(1/2) - 1 = -0.5 = 0xFC000000$ _{5.23} Format

For this example it is assumed that a net processing gain of 2^4 (24 dB) is realized from the SAP input and the DRC (which is identical to the net processing gain assumed for Example 1). The 2^4 gain results in reducing the 8-bit headroom in the 48-bit DAP word to a headroom of four bits. The 32-bit data into the DRC then resides in bits 27:0, which means that the data level into the DRC is down 24 dB with respect to the input level at the SAP. Data input into the TAS3103 (SAP) at a level of -148.7 dB is seen as a $-148.7 \text{ dB} - 24 \text{ dB} = -172.7\text{-dB}$ signal at the DRC. T1 and T2 must be set to -172.7 dB to realize a common threshold point at an incoming signal level of -148.7 dB .

Figure 3–25 shows the transfer function resulting from entering the I²C coefficient values given in Table 3–6. At the T1/T2 threshold, a discontinuity of 30 dB is observed. For inputs above the threshold, the transfer curve is horizontal (infinite compression), and the horizontal line starts 20 dB above the 1:1 transfer curve at the threshold point. Thus, for cases when $T1 = T2$, O2 governs the offset with regard to the starting point of the transfer curve above the common threshold point and k2 determines the slope of the transfer curve. For inputs below the common threshold point, the transfer curve exhibits a 2:1 compression and starts 10 dB below the 1:1 transfer curve. Thus, O1 sets the offset at the threshold point for the transfer curve at and below the common threshold point and k0 determines the slope of this curve. Slope parameter k1 plays no role when $T1 = T2$. The value of 0 (1:1 transfer) used in this example for k1 could be changed to any value and the resulting transfer function would not be altered. The change from a 2:1 compression to a 1:1 transfer at -192 dB is due to 32-bit dynamic range saturation at the DRC input.

Figure 3-25. DRC Transfer Curve—Example 3

The horizontal slope of the transfer curve above the common threshold point does not remain horizontal indefinitely. At a point 158 dB above the common threshold point (–14.7-dB DRC input level), the transfer function has gone from a boost of 20 dB to a cut of 138 dB. A cut of 138 dB is the maximum cut possible for a 5.23 format gain coefficient ($2^{-23} \geq 23 \text{ octaves} \times 6 \text{ dB/octave} = 138 \text{ dB}$). Thus, at a DRC input level of –14.7 dB, minimum gain saturation has been reached. For inputs above this saturation point, the DRC-derived gain coefficient remains constant at the minimum gain value (2^{-23}), and the transfer function exhibits a 1:1 transfer slope.

3.7.3.4 Example 4—Expansion/Cut/Expansion With Gain Saturation and 32-Bit Dynamic Range Saturation

The three previous examples restricted the slope factor k to lie in the range $k \geq -1$. This example illustrates the transfer characteristic obtained using a value of k less than -1 . For this example it is assumed that the net processing gain into the DRC is 0 dB. This means that the 8-bit headroom in the 48-bit DAP processing word structure does not contain data. Since the DRC receives the upper 32 bits of this 48-bit word, data at the DRC is down 48 dB (8 bits \times 6 dB/bit = 48 dB) with respect to the signal level at the SAP input (TAS3103 input). The transfer function parameters for this example are given in Table 3–7. Figure 3–26 shows the transfer function resulting from entering the I²C coefficient values given in Table 3–7.

At the threshold point T2 (–70 dB), the transfer function is 100 dB below the 1:1 transfer slope ($O_2 = 100 \text{ dB}$). For input levels above T2, the transfer function exhibits a 1:1.4 expansion. For input levels below T2, the transfer function exhibits a negative slope; for every dB the input decreases, the output increases by 1 dB. At an input level 62 dB below T2 (–132 dB), the transfer curve has risen 62 dB, for a net boost of 124 dB. The transfer curve at this input level is 24 dB above the 1:1 transfer curve. This boost value puts the DRC-derived gain coefficient into gain saturation. For input levels below –132 dB, the gain coefficient remains constant at maximum gain and the transfer function exhibits a 1:1 transfer slope, parallel to the 1:1 transfer curve but 24 dB above it.

At T1 (–150 dB), the transfer curve snaps back to the 1:1 transfer curve since $O_1 = 0 \text{ dB}$. The DRC gain coefficient is no longer in gain saturation and for inputs below –150 dB, the transfer function exhibits a 1:1.5 expansion. The change from a 1:1.5 expansion to a 1:1 transfer below –192 dB is the result of 32-bit dynamic range saturation.

Figure 3–26. DRC Transfer Curve—Example 4

Table 3–7. DRC Example 4 Parameters

DRC PARAMETER	REQUIRED (SPECIFIED) VALUE (NET GAIN _{SAP Input-DRC} = 0 dB)	I ² C COEFFICIENT VALUE
T2	-22 dB _{Input} ≥ -70 dB _{DRC}	$-70/-6.0206 = 11.626748$ = 0x000005D03948 _{25.23} Format
T1	-102 dB _{Input} ≥ -150 dB _{DRC}	$-150/-6.0206 = 24.91446$ = 0x00000C750D09 _{25.23} Format
O2	100 dB	$(100 + 24.0824)/6.0206 = 20.609640$ = 0x00000A4E08B0 _{25.23} Format
O1	0 dB	$(0 + 24.0824)/6.0206 = 4.000000$ = 0x000002000000 _{25.23} Format
k2	1:1.4 Expansion	$1.4 - 1 = 0.4 = 0X03333333$ _{5.23} Format
k1	1:-1 Transfer	$(1/-1) - 1 = -1 - 1 = -2 = 0XF0000005$ _{5.23} Format
k0	1:1.5 Expansion	$1.5 - 1 = 0.5 = 0x04000005$ _{5.23} Format

3.8 Spectrum Analyzer/VU Meter

The TAS3103 contains an I²C bus programmable function block that can serve as either a spectrum analyzer or a volume unit (VU) meter. Figure 3–26 shows the structure of this function block and lists the I²C subaddress of the parameters that control it.

The block consists of 10 biquad filters, each followed by an rms estimator and a logarithmic converter. Two nodes provide input to the block, with each node servicing five of the 10 biquad filters. Audio from input node s can either come exclusively from channel 1, channel 2, channel 3, or from a gain-weighted combination of these channels. Audio from input node t can also come exclusively from either channel 1, channel 2, or channel 3, or from a gain-weighted combination of these channels. The spectrum analyzer then can be used to divide the audio frequency band into ten frequency bins to examine the spectrum of the audio data stream on channel 1, channel 2, channel 3, or any combination of these channels. The spectrum analyzer can also be used to divide the audio frequency band into five frequency bins to examine the spectral content of two of the channels independently.

The VU meter is a special case of the spectrum analyzer that uses only the outputs from biquad 5 and biquad 6. Typically, for the VU meter, one channel would be routed to biquad 5 (node s) and a different channel would be routed to biquad 6 (node t). Each biquad filter would be assigned a band pass transfer function that encompasses most of the audio band, or the filter could be configured as a pass-through device to see the full spectral band. The two outputs then would be a measure of the energy on the two channels. Other options for the VU meter are also available. For example, by properly setting the coefficients on biquad 5 and biquad 6, the concurrent measurement of bass and treble volume levels on a single channel could be made.

Mixer and summation elements preceding the two input nodes s and t provide a means of adjusting the spectrum analyzer and VU meter outputs relative to the incoming audio data stream. The spectrum analyzer and VU meter outputs are unsigned 5.3 format base 2 logarithmic numbers. The integer part of the number designates the most significant bit (in the 48-bit digital audio processor – DAP – word) occupied by the magnitude of the rms estimate of the biquad filter output. A value of 31 means the magnitude of the rms estimate occupies bit 47 of the 48-bit DAP word (bit 48 is the sign bit, and using the absolute value of the biquad filter output in determining the rms estimate makes this bit always 0 in value). A value of 30 means the magnitude of the rms estimate occupies bit 46 and this pattern continues with a value of 1 signifying the magnitude of the rms estimate occupies bit 17. A value of 0 signifies that the magnitude of the rms estimate is below bit 17. The fractional digits in the 5.3 formatted number are simply the three bits below the most significant data bit. If the rms estimate lies below bit 16 of the 48-bit DAP word, the spectrum analyzer/VU meter output is 0.0. Figure 3–27 gives examples of logarithmic outputs for different 48-bit rms estimate values.

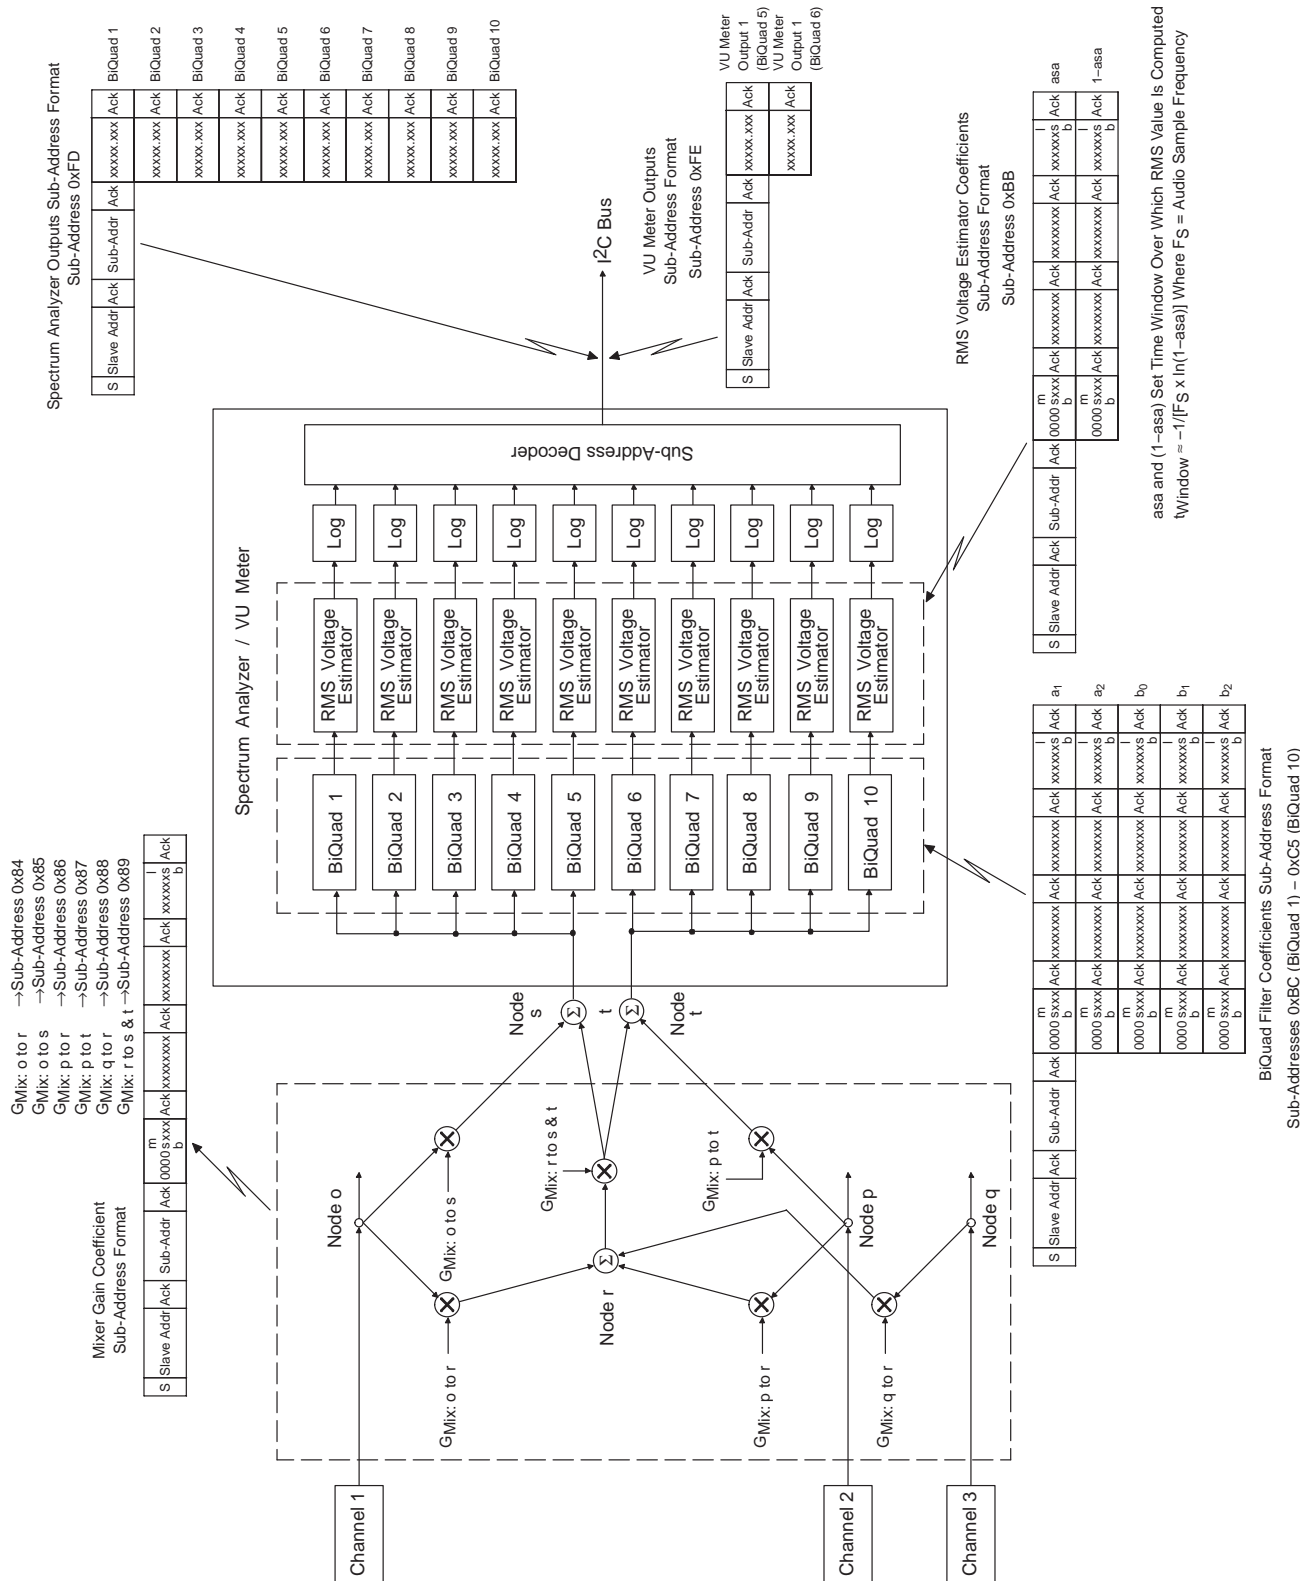

Figure 3-27. Spectrum Analyzer/VU Meter Block Diagram

Figure 3–28. Logarithmic Number Conversions—Spectrum Analyzer/VU Meter

The time window over which the rms estimate is conducted is programmable via the I²C bus (subaddress 0xBB). The time window for a given set of coefficients is approximately:

$$t_{\text{Window}} \approx -\frac{1}{F_S \ln(1 - \text{asa})}$$

Where F_S is the audio sample rate and asa is a 5.23 format number. The variable asa (and $1 - \text{asa}$) must be kept within the range of greater than zero and less than one. The time constant programmed applies to all 10 rms estimate blocks.

CAUTION: The spectrum analyzer and VU meter functions are only accessible in the I²C slave mode.

3.9 Dither

The TAS3103 provides a dither block for adding triangular or quadratic (sum of two uncorrelated triangular distributions) distributed noise to the processed audio data stream prior to routing to the output serial audio port (SAP). Each of the three monaural channels in the TAS3103 has its own dedicated dither data stream that is statistically independent from the dither data streams used by the other two monaural channels. The statistical distribution of the dither data stream, triangular or quadratic, is selectable, but the selection made applies to the dither data streams for all three monaural channels. Each monaural channel is also assigned a mixer for adjusting the level at which the dither data stream is inserted into the audio data stream.

Figure 3–29 is a detailed block diagram of the dither block. Five subaddresses are used to fully configure the dither blocks and the associated channel mixers. In the I²C master mode, these dither parameters are set by the EEPROM content and cannot be subsequently changed.

3.9.1 Dither Seeds

The dither circuit consists of two linear feedback shift registers—LFSR1 and LFSR2. The dither seed subaddress (0xC7) consists of a byte-wide seed for LFSR1 (bits 7:0) and a byte-wide seed for LFSR2 (bits 15:8). The seeds serve to define the starting point of each LFSR sequence, but not the feedback structure itself. Each linear feedback shift register (LFSR) is a 26-bit structure that runs off the digital audio processor (DAP) clock. For a maximum DAP clock frequency of 135.168 MHz [12.288 MHz (MCLKI) x 11 (PLL multiplier)], the 26-bit LFSR has a cycle time of 496.5 ms ($2^{26}/135.168$ MHz). LFSR1 and LFSR2 use the same feedback structure but different taps for outputting. As long as the seeds for the two LFSRs are not ± 13 counts apart (in which case the two different sets of output taps would correlate), any set of seed values for LFSR1 and LFSR2 is suitable.

When two or more TAS3103s are powered by the same supply, a concern as to whether or not there is correlation between the dither data streams on different chips arises. At power turn on, a TAS3103 does not begin the dither process until reset is deactivated. If the TAS3103s are reset by the internal power good signals from the internal regulators, the chip-to-chip variance of the logic voltage threshold point at which the power good signal is deactivated assures, with a high probability, that the dither data streams between chips are uncorrelated. However, when an external logic-driven reset is applied to the TAS3103s, the probability of correlation between the dither data streams on different chips after the rest is removed significantly increases. For this reason, the dither seeds have been made programmable via the I²C bus.

Figure 3–29. Dither Data Block Diagram

When updating multiple TAS3103s with dither seeds, timing should be taken into account. The recommended seed update process is to load all TAS3103s with their seed values in less time than the minimum LFSR cycle time of 496.5 ms, and use the same set of seeds for all TAS3103s. Each TAS3103 immediately begins running, starting at the state set by the new seed, upon receiving the new seed. The sequential delivery, in time, of the seeds to the multiple TAS3103s assures the TAS3103s do not all start with their new seeds at the same time, and the completion of the process in less than 496.5 ms assures that previously programmed TAS3103s are not repeating the cycle at the same time another TAS3103 is being programmed with the same seed set—causing correlation between the dither data streams of the two TAS3103s.

CAUTION: The state of the digital audio processor may prevent the loading of a new I²C—commanded dither seed value. Anytime a new seed is loaded into the TAS3103 via an I²C write transaction to address 0xC7, it must be followed by an I²C read transaction to address 0xC7 to verify that the new seed value was accepted. If the new seed was not accepted, the write-read sequence must be repeated.

3.9.2 Dither Mix Options

In Figure 3–29 it is seen that the two LFSRs are logically combined to produce a triangular probability distribution. This distribution is then sampled at six different points in time, by the DAP processing clock, to create six statistically independent data streams. Sampling the LFSR outputs at different points in time within an audio sample period (1/LRCLK) assures the six dither data streams are uncorrelated. The six uncorrelated dither data streams are then routed through mixers. Each pair of mixer outputs is then applied to a summation block. It is noted in Figure 3–29 that each of the three mixers pairs has the same set of coefficients (set by I²C subaddress 0xC6). If the coefficients for both mixers are set to 1.0, a quadratic distribution is obtained. If either coefficient is set to 0.0, a triangular distribution is obtained. If both coefficients are set to 0.0, dither is disabled.

3.9.3 Dither Gain Mixers

Figure 3–29 shows the peak magnitude of the triangular distribution to be ±16 in the 48-bit DAP word (25.23 format). The peak magnitude of the quadratic dither data is twice this, or ±32. Figure 3–30 shows the position of this peak magnitude value in reference to the DAP 48-bit data word. Table 3–8 lists the mixer gains required to position the dither data stream at the LSB of the output data word for different data sample word sizes.

Table 3–8. Mixer Gain Setting for LSB Dither Data Insertion

DISTRIBUTION	MIXER GAIN COEFFICIENT				
	32-BIT SAMPLE	24-BIT SAMPLE	20-BIT SAMPLE	18-BIT SAMPLE	16-BIT SAMPLE
Triangular	2^{-19}	2^{-11}	2^{-7}	2^{-5}	2^{-3}
Quadratic	2^{-20}	2^{-12}	2^{-8}	2^{-6}	2^{-4}

Figure 3–30. Dither Data Magnitude (Gain = 1.0)

3.9.4 Dither Statistics

Figure 3–31 presents plots of the autocorrelation and channel-to-channel correlation properties of the dither data stream when configured as triangular distributed noise. Figure 3–31(a) is the circular autocorrelation of 16K samples of dither data collected from the TAS3103. The audio signal level was set to zero, and the dither data stream was inserted at the LSB of the output word. The autocorrelation contains a single line of value 8000, at the point of correlation, and random noise terms of approximately ± 150 counts in value. The value 8000 agrees with the selection of the triangular distribution—50% of the 16K dither output samples are of value ± 1 . Figure 3–31(b) is the circular correlation of 16K samples of dither data from CH1 and 16K samples of dither data from CH2. There are no points of correlation in this plot, verifying that the two data streams are uncorrelated. The random noise terms are again approximately ± 150 counts in value

(a) Auto-Correlation Plot – CH1

(b) Correlation Plot – CH2 and CH3

Figure 3–31. Triangular Dither Statistics

Figure 3–32 presents plots of the autocorrelation and channel-to-channel correlation properties of the dither data stream when configured as quadratic distributed noise. Figure 3–32(a) is the circular autocorrelation of 16K samples of dither data collected from the TAS3103. The audio signal level was set to zero and the dither data stream was inserted at the LSB+1 level of the output word. The autocorrelation contains a single line of value 16,000 at the point of correlation and random noise terms of approximately ± 300 counts in value. The value 16,000 agrees with the

selection of the quadratic distribution—50% of the 16K dither output samples are of value ± 1 ($0.5 \times 1^2 \times 16,000 = 8000$) and 12.5% of the 16K dither output samples are ± 2 ($0.125 \times 2^2 \times 16,000 = 8000$). Figure 3–32(b) is the circular correlation of 16K samples of dither data from CH2 and 16K samples of dither data from CH3. There are no points of correlation in this plot, verifying that the two data streams are uncorrelated. The random noise terms are approximately ± 300 counts in value, as the dither data pattern was inserted at the LSB+1 bit of the output word instead of the LSB bit, as was the case for triangular dither.

(b) Correlation Plot – CH2 and CH3

Figure 3–32. Triangular Dither Statistics

3.10 Output Crossbar Mixers

The TAS3103 has three serial output ports—SDOUT1, SDOUT2 and SDOUT3. Each serial output port is assigned two processing nodes within the TAS3103. One of the two nodes sources the left stereo data sample and the other node sources the right stereo data sample. Figure 3–33 shows the assignment of these internal nodes to the serial output ports. Two cases are shown in Figure 3–33—discrete mode and TDM mode. The discrete mode connections are straightforward, but the TDM connections are considerably more involved in order to support the different one-chip and two-chip TDM modes (see the *Input and Output Serial Port (SAP)* section for more discussion on the TDM modes).

The purpose of the output crossbar is to give each of the three monaural channels in the TAS3103 access to any of the six internal processing nodes (U, V, W, X, Y, and Z) that supply data to the three serial output ports. This flexibility in the routing of the monaural channel outputs to the serial output ports, coupled with the flexibility in the routing of the serial input ports to the monaural channels, fully decouples the input data from the output data. A given process flow and output data topology can be obtained from any ordering of data into the TAS3103.

Figure 3–34 shows the output crossbar mixer topology. Each monaural channel feeds six mixers. The six mixers, in turn, feed the six output nodes U, V, W, X, Y, and Z. A given monaural channel can thus be connected to either the left or right side of SDOUT1, SDOUT2 and SDOUT3.

The mixers, although capable of performing boost (gain) and cut (attenuation) on the outgoing audio, are typically used to facilitate on / off switching (a 5.23 format coefficient value of 0x0800000 turns the mixer on and a coefficient value of 0x0000000 turns the mixer off). The audio data streams at the input to these mixers include dither, and any boost or cut in the audio at this point affects the dither levels as well.

Node r in Figure 3–34 provides a means of outputting a post-processed sum of the audio on channel 1 and channel 2. This capability could be used to generate a center audio component from L and R components being processed on channels 1 and 2. This would allow channel 3 to be a sub-woofer channel. Node r could also be used to create a subwoofer channel, assuming an active subwoofer with filtering capability is receiving the subwoofer output. This option would then free channel 3 for center channel processing.

4 Electrical Specifications

4.1 Absolute Maximum Ratings Over Operating Temperature Ranges (unless otherwise noted)†

Supply voltage range:	V _{DDS}	-0.5 to 3.8 V
	A_V _{DDS}	-0.5 to 3.8 V
Input voltage range, V _I :	3.3-V LVCMOS	-0.5 V to V _{DDS} + 0.5 V
	1.8-V LVCMOS	-0.5 V to AV _{DD} (¹) + 0.5 V
Output voltage range, V _O :	3.3-V LVCMOS	-0.5 V to V _{DDS} + 0.5 V
	1.8-V LVCMOS	-0.5 V to DV _{DD} (²) + 0.5 V
	1.8-V LVCMOS	-0.5 V to AV _{DD} (³) + 0.5 V
Input clamp current, I _{IK} (V _I < 0 or V _I > DV _{DD})		±20 mA
Output clamp current, I _{OK} (V _O < 0 or V _O > DV _{DD})		±20 mA
Operating free-air temperature (Commercial)		0°C to 70°C
Operating free-air temperature (Industrial)		-40°C to 85°C
Storage temperature range, T _{stg}		-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds		260°C

† Stresses beyond those listed under “absolute maximum ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under “recommended operating conditions” is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

- NOTES:
1. AV_{DD} is a 1.8-V supply derived from a regulator in the TAS3103 chip. Pin XTALI is the only TAS3103 input that is referenced to this 1.8 V logic supply. The absolute maximum rating listed is for reference; only a crystal should be connected to XTALI.
 2. DV_{DD} is a 1.8-V supply derived from regulators internal to the TAS3103 chip. DV_{DD} is routed to pin 29 (DV_{DD}_BYPASS_CAP) to provide access to external filter capacitors, but should not be used to source power to external devices.
 3. Pin XTALO is the only TAS3103 output that is derived from the internal 1.8-V logic supply AV_{DD}. The absolute maximum rating listed is for reference; only a crystal should be connected to XTALO. AV_{DD} is also routed to pin 6 (AV_{DD}_BYPASS_CAP) to provide access to external filter capacitors, but should not be used to source power to external devices.

DISSIPATION RATING TABLE (High-k Board, 105°C Junction)

PACKAGE	T _A ≤ 25°C POWER RATING	OPERATING FACTOR ABOVE T _A = 25°C	T _A = 85°C POWER RATING

			No LRCLK, SCLK, or MCLKI/XTALI		1.5		

NOTES: 4. Value given is for those input pins that connect to an internal pullup resistor as well as an input buffer. For inputs that have a pulldown resistor or no resistor, I_{IL} is ±1 μA.

5. Value given is for those input pins that connect to an internal pulldown resistor as well as an input buffer. For inputs that have a pullup resistor or no resistor, I_{IH} is ±1 μA.

4.4 TAS3100 Timing Characteristics

4.4.1 Master Clock Signals Over Recommended Operating Conditions (Unless Otherwise Noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNITS
$f_{(XTALI)}$	Frequency, XTALI ($1/t_{c(1)}$)		2.8		20	MHz
$f_{(MCLKI)}$	Frequency, MCLKI ($1/t_{c(2)}$)		2.8		25	MHz
$t_w(MCLKI)$	Pulse duration, MCLKI high	See Note 6	$H_{MCLKI} - 25$	H_{MCLKI}	$H_{MCLKI} + 25$	ns
MCLKI jitter					± 5	ns
$f_{(MCLKO)}$	Frequency, MCLKO ($1/t_{c(3)}$)		2.8		25	MHz
$t_r(MCLKO)$	Rise time, MCLKO	$C_L = 30$ pF			9.5	ns
$t_f(MCLKO)$	Fall time, MCLKO	$C_L = 30$ pF			9.5	ns
$t_w(MCLKO)$	Pulse duration, MCLKO high	See Note 9	H_{MCLKO}			ns
MCLKI jitter	XTALI master clock source		80			ps
	MTALI master clock source	See Note 10				
$t_d(MI-MO)$	Delay time, MCLKI rising edge to MCLKO rising edge	MCKLO = MCLKI	See Note 7		17	ns
		MCKLO < MCLKI	See Note 7 and Note 8		17	ns

- NOTES:
- $H_{MCLKI} = 1 / 2MCLKI$
 - Only applies when MCLKI is selected as master source clock.
 - Also applies to MCLKO falling edge when $MCKLO = MCLKI/2$ or $MCLKI/4$
 - $H_{MCLKO} = 1 / 2MCKLO$. MCLKO has the same duty cycle as MCLKI when $MCKLO = MCLKI$. When $MCKLO = 0.5 MCLKI$ or $0.25 MCLKI$, the duty cycle of MCLKO is typically 50%.
 - When MCLKO is derived from MCLKI, $MCLKO$ jitter = MCLKI jitter

Figure 4–1. Master Clock Signals Timing Waveforms

4.4.2 Control Signals Over Recommended Operating Conditions (Unless Otherwise Noted)

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNITS
$t_{w1(L)}$ Pulse duration, \overline{RST} low		10			ns
t_{pd1} Propagation delay, PWRDN high to power down state asserted	See Note 11				μ s
t_{pd2} Propagation delay, PWRDN low to power down state deasserted	See Note 12				μ s

NOTES: 11. The maximum worst case value for t_{pd1} is given by

$$t_{pd1_worst_case} = \frac{4096 + GPIOFSCOUNT}{LRCLK} + \frac{80}{\text{Microprocessor_Clock}}$$

12. t_{pd2} is determined by the time it takes the internal digital PLL to reach a locked condition, which, in turn, is governed by the MCLKI/XTALI frequency and the PLL output frequency. For a 135-MHz PLL output and an MCLKI value of 24.576 MHz, t_{pd2} is typically 25 μ s. For an 11.264-MHz PLL output clock and a 1.024-MHz MCLKI/XTALI master clock, t_{pd2} is typically 360 μ s.

Figure 4–2. Control Signals Timing Waveforms

4.4.3 Serial Audio Port Slave Mode Signals Over Recommended Operating Conditions (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNITS
f_{LRCLK}	Frequency, LRCLK (F_S)		8		96	kHz
$t_w(SCLKIN)$	Pulse duration, SCLKIN high	See Note 14	$0.25 H_{SCLKIN}$	H_{SCLKIN}	$0.75 H_{SCLKIN}$	ns
f_{SCLKIN}	Frequency, SCLKIN	See Note 13	$32F_S$		25	MHz
t_{cyc}	Cycle time, SCLKIN	See Note 13	40		$1/32F_S$	ns
t_{pd1}	Propagation delay, SCLKIN falling edge to SDOUT				15.1	ns
t_{su1}	Setup time, LRCLK to SCLKIN rising edge		6.6			ns
t_{h1}	Hold time, LRCLK from SCLKIN rising edge		0			ns
t_{su2}	Setup time, SDIN to SCLKIN rising edge		1.15			ns
t_{h2}	Hold time, SDIN from SCLKIN rising edge		2.3			ns
t_{pd2}	Propagation delay, SCLKIN falling edge to SCLKOUT2 falling edge	SCLKOUT2 = SCLKIN			12.4	ns
		SCLKOUT2 < SCLKIN			12.5	ns

NOTES: 13. Typical duty cycle is 50/50.
 14. $H_{SCLKIN} = 1/2f_{SCLKIN}$

Figure 4–3. Serial Audio Port Slave Mode Timing Waveforms

4.4.4 Serial Audio Port Master Mode Signals Over Recommended Operating Conditions (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNITS
$f_{(LRCLK)}$	Frequency LRCLK		8		96	kHz
$t_{r(LRCLK)}$	Rise time, LRCLK	$C_L = 30 \text{ pF}$			11.4	ns
$t_{f(LRCLK)}$	Fall time, LRCLK	$C_L = 30 \text{ pF}$			11.2	ns
$f_{(SCLKOUT)}$	Frequency ($1/t_{cyc}$), SCLKOUT1/SCLKOUT2	See Note 13	$32F_S$		25	MHz
$t_{r(SCLKOUT)}$	Rise time, SCLKOUT1/SCLKOUT2	$C_L = 30 \text{ pF}$			9.5	ns
$t_{f(SCLKOUT)}$	Fall time, SCLKOUT1/SCLKOUT2	$C_L = 30 \text{ pF}$			9.8	ns
$t_{pd1(SCLKOUT1)}$	Propagation delay, SCLKOUT1 falling edge to LRCLK edge				4.1	ns
$t_{pd1(SCLKOUT2)}$	Propagation delay, SCLKOUT2 falling edge to LRCLK edge				4.3	ns
t_{pd2}	Propagation delay, SCLKOUT2 falling edge to SDOUT				3.4	ns
t_{su}	Setup time, SDIN to SCLKOUT1 rising edge		18.4			ns
t_h	Hold time, SDIN from SCLKOUT1 rising edge		23			ns
t_{sk}	Skew time, SCLKOUT1 to SCLKOUT2			0.8	3	ns

NOTE 13: Typical duty cycle is 50/50.

Figure 4–4. TAS3100 Serial Audio Port Master Mode Timing Waveforms

4.4.5 I²C Slave Mode Interface Signals Over Recommended Operating Conditions (unless otherwise noted)

PARAMETER	TEST CONDITIONS	STANDARD MODE			FAST MODE			UNITS
		MIN	TYP	MAX	MIN	TYP	MAX	
f _{SCL}	Frequency, SCL		0	100		0	400	kHz
t _{w(H)}	Minimum pulse duration, SCL high	See Note 15		0.43		0.12		μs
t _{w(L)}	Minimum pulse duration, SCL low	See Note 15		1.3		0.9		μs
t _r	Rise time, SDA _{Output}	C _L = 330 pF		48.3		48.3		ns
t _f	Fall time, SDA _{Output}	C _L = 330 pF		35.9		35.9		ns
t _{su1}	Setup time, SDA _{Input} to SCL	See Note 15		0		0		ns
t _{h1}	Hold time	SCL to SDA _{Input}	See Note 15		0		0	ns
		SCL to SDA _{Output}	See Note 16	T _{oversamp}	2T _{oversamp}	T _{oversamp}	2T _{oversamp}	μs
t _{buf}	Minimum bus free time between STOP and START condition	See Note 15		0.82		0.38		μs
t _{su2}	Minimum setup time, SCL to START condition	See Note 15		0.7		0.4		μs
t _{h2}	Minimum hold time, START condition to SCL	See Note 15		1.5		0.05		μs
t _{su3}	Minimum setup time, SCL to STOP condition	See Note 15		0.9		0.4		μs

NOTES: 15. The maximum and/or minimum values for the TAS3103 I²C port parameters meets those characteristics of the SDA and SCL bus lines listed below, as specified in the I²C bus devices bus specification.

16. T_{oversamp} is the period of the oversample clock provided to the I²C master slave controller. This clock is dependent on the microprocessor clock setting and the value set for the variable N in subaddress 0xFB. See Figure 2–14.

SPECIFIED I ² C BUS CHARACTERISTICS

NOTE 1: GPIO ports are initialized to be read ports. The initial input values read then are dependent on what is connected to the GPIO pins. If a given GPIO pin is left unconnected, the internal pullup results in a logic 1 being read.

A.2 TAS3103 Firmware Block Diagram

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead/Ball Finish (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
TAS3103DBT	NRND	TSSOP	DBT	38	50	Green (RoHS & no Sb/Br)	CU NIPDAU	Level-2-260C-1 YEAR	0 to 70	TAS3103	
TAS3103DBTG4	NRND	TSSOP	DBT	38	50	Green (RoHS & no Sb/Br)	CU NIPDAU	Level-2-260C-1 YEAR	0 to 70	TAS3103	
TAS3103DBTR	NRND	TSSOP	DBT	38	2000	Green (RoHS & no Sb/Br)	CU NIPDAU	Level-2-260C-1 YEAR	0 to 70	TAS3103	
TAS3103DBTRG4	NRND	TSSOP	DBT	38	2000	Green (RoHS & no Sb/Br)	CU NIPDAU	Level-2-260C-1 YEAR	0 to 70	TAS3103	

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSELETE: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

PLASTIC SMALL OUTLINE

- NOTES:
- All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M-1994.
 - This drawing is subject to change without notice.
 - Body dimensions do not include mold flash or protrusion.
 - Falls within JEDEC MO-153.

- NOTES:
- A. All linear dimensions are in millimeters.
 - B. This drawing is subject to change without notice.
 - C. Publication IPC-7351 is recommended for alternate designs.
 - D. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC-7525.
 - E. Customers should contact their board fabrication site for solder mask tolerances between and around signal pads.

IMPORTANT NOTICE

Texas Instruments Incorporated (TI) reserves the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete.

TI's published terms of sale for semiconductor products (<http://www.ti.com/sc/docs/stdterms.htm>) apply to the sale of packaged integrated circuit products that TI has qualified and released to market. Additional terms may apply to the use or sale of other types of TI products and services.

Reproduction of significant portions of TI information in TI data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such reproduced documentation. Information of third parties may be subject to additional restrictions. Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyers and others who are developing systems that incorporate TI products (collectively, "Designers") understand and agree that Designers remain responsible for using their independent analysis, evaluation and judgment in designing their applications and that Designers have full and exclusive responsibility to assure the safety of Designers' applications and compliance of their applications (and of all TI products used in or for Designers' applications) with all applicable regulations, laws and other applicable requirements. Designer represents that, with respect to their applications, Designer has all the necessary expertise to create and implement safeguards that (1) anticipate dangerous consequences of failures, (2) monitor failures and their consequences, and (3) lessen the likelihood of failures that might cause harm and take appropriate actions. Designer agrees that prior to using or distributing any applications that include TI products, Designer will thoroughly test such applications and the functionality of such TI products as used in such applications.

TI's provision of technical, application or other design advice, quality characterization, reliability data or other services or information, including, but not limited to, reference designs and materials relating to evaluation modules, (collectively, "TI Resources") are intended to assist designers who are developing applications that incorporate TI products; by downloading, accessing or using TI Resources in any way, Designer (individually or, if Designer is acting on behalf of a company, Designer's company) agrees to use any particular TI Resource solely for this purpose and subject to the terms of this Notice.

TI's provision of TI Resources does not expand or otherwise alter TI's applicable published warranties or warranty disclaimers for TI products, and no additional obligations or liabilities arise from TI providing such TI Resources. TI reserves the right to make corrections, enhancements, improvements and other changes to its TI Resources. TI has not conducted any testing other than that specifically described in the published documentation for a particular TI Resource.

Designer is authorized to use, copy and modify any individual TI Resource only in connection with the development of applications that include the TI product(s) identified in such TI Resource. NO OTHER LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE TO ANY OTHER TI INTELLECTUAL PROPERTY RIGHT, AND NO LICENSE TO ANY TECHNOLOGY OR INTELLECTUAL PROPERTY RIGHT OF TI OR ANY THIRD PARTY IS GRANTED HEREIN, including but not limited to any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information regarding or referencing third-party products or services does not constitute a license to use such products or services, or a warranty or endorsement thereof. Use of TI Resources may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

TI RESOURCES ARE PROVIDED "AS IS" AND WITH ALL FAULTS. TI DISCLAIMS ALL OTHER WARRANTIES OR REPRESENTATIONS, EXPRESS OR IMPLIED, REGARDING RESOURCES OR USE THEREOF, INCLUDING BUT NOT LIMITED TO ACCURACY OR COMPLETENESS, TITLE, ANY EPIDEMIC FAILURE WARRANTY AND ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, AND NON-INFRINGEMENT OF ANY THIRD PARTY INTELLECTUAL PROPERTY RIGHTS. TI SHALL NOT BE LIABLE FOR AND SHALL NOT DEFEND OR INDEMNIFY DESIGNER AGAINST ANY CLAIM, INCLUDING BUT NOT LIMITED TO ANY INFRINGEMENT CLAIM THAT RELATES TO OR IS BASED ON ANY COMBINATION OF PRODUCTS EVEN IF DESCRIBED IN TI RESOURCES OR OTHERWISE. IN NO EVENT SHALL TI BE LIABLE FOR ANY ACTUAL, DIRECT, SPECIAL, COLLATERAL, INDIRECT, PUNITIVE, INCIDENTAL, CONSEQUENTIAL OR EXEMPLARY DAMAGES IN CONNECTION WITH OR ARISING OUT OF TI RESOURCES OR USE THEREOF, AND REGARDLESS OF WHETHER TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

Unless TI has explicitly designated an individual product as meeting the requirements of a particular industry standard (e.g., ISO/TS 16949 and ISO 26262), TI is not responsible for any failure to meet such industry standard requirements.

Where TI specifically promotes products as facilitating functional safety or as compliant with industry functional safety standards, such products are intended to help enable customers to design and create their own applications that meet applicable functional safety standards and requirements. Using products in an application does not by itself establish any safety features in the application. Designers must ensure compliance with safety-related requirements and standards applicable to their applications. Designer may not use any TI products in life-critical medical equipment unless authorized officers of the parties have executed a special contract specifically governing such use. Life-critical medical equipment is medical equipment where failure of such equipment would cause serious bodily injury or death (e.g., life support, pacemakers, defibrillators, heart pumps, neurostimulators, and implantables). Such equipment includes, without limitation, all medical devices identified by the U.S. Food and Drug Administration as Class III devices and equivalent classifications outside the U.S.

TI may expressly designate certain products as completing a particular qualification (e.g., Q100, Military Grade, or Enhanced Product). Designers agree that it has the necessary expertise to select the product with the appropriate qualification designation for their applications and that proper product selection is at Designers' own risk. Designers are solely responsible for compliance with all legal and regulatory requirements in connection with such selection.

Designer will fully indemnify TI and its representatives against any damages, costs, losses, and/or liabilities arising out of Designer's non-compliance with the terms and provisions of this Notice.
